Addresses.

MORIAL TO THE LATE J. T. ESKRIDGE,
M.D., OF DENVER, COLO.

CHAIRMAN OF THE SECTION ON NEUROLOGY OF THE
AMERICAN MEDICAL ASSOCIATION.*

CHARLES K. MILLS, M.D.
PHILADELPHIA.

AND

FRANK P. NORBURY, M.D.
JACKSONVILLE, ILL.

ADDRESS BY DR. MILLS.

Through the death of Dr. J. T. Eskridge Jan. 17, 1902, this Section has been deprived of a chairman than whom none could have filled the position more worthily. In spite of ill health, Dr. Eskridge started the work of preparing for this meeting just before his last illness. He was in his fifty-fifth year at the time of his death. He graduated in 1875 at the Jefferson Medical College, Philadelphia, and, after nine years filled with hard work and high ambition spent in that city, he went, because of ill health in 1884, to Colorado. He was one of the founders of the Philadelphia Neurological Society. During his brief medical career in Philadelphia he held many important positions in the hospitals and medical institutions of that city and took active part in the proceedings of its medical societies, to which and in the medical journals of that period he was a frequent contributor. His most important and enduring work, however, was done in the far west. Probably no one west of the Mississippi has stamped his name so indelibly in the history of neurology. He stands, indeed, among the foremost neurologists in the entire country.

Dr. Eskridge was a member of a number of the most important national medical organizations, in all of which he took a deep interest, but in none more than in the American Medical Association, to whose proceedings he frequently contributed. When the American Medical Association met in Colorado in 1899 he was among those who took the warmest interest in welcoming the members of the Association to that state.

He was Professor of Neurology in the Denver University and in the University of Colorado, and was Dean of the Medical Faculty of the latter institution. He was a member and at one time president of the Colorado State Medical Society. He was a member of the American Neurological Association, the American Medico-Legal Society, the American Academy of Railway Surgeons and the American Medico-Psychological Association. At the time of his death he was first vice-

president of the American Neurological Association. Dr Eskridge's contributions to medical literature, chiefly to neurology and medical jurisprudence, were numerous and of a high order. In his writings, as in the practice of his profession, he was distinguished for the carefulness and thoroughness of his work. As a neurologic diagnostician he had few equals. As a medical jurist he was equally respected by the legal and medical professions. As a medical witness, as a teacher and as a writer he was honest in his convictions and in his expression of them. After his health broke down in 1884 it was never fully restored, yet he pursued his ends, which were always honorable, with an untiring zeal. In private life he was retiring and of a kindly disposition. His death is a great loss, not only to neurology and the medical profession, but to the community in which he lived and labored.

ADDRESS OF DR. NORBURY.

The strangely fascinating influence thrown out by the enthusiasts in all professions strikes a sympathetic chord in the heart of the student, touches and dominates his eagerness for knowledge and gives to him that which we call inspiration. It is this inspiration which imparts zeal, which in its turn lends to knowledge that wonderful power for good, that essential for achievement—enthusiasm. "Knowledge without zeal sits in its study, plays with its books and does nothing," but when under the influence of the magic power of working enthusiasm, it accomplishes great things.

All great achievements in life have been accomplished by enthusiasts, zealous in their works and keeping in view the three elements which Abbott says are necessary to real success in life, viz.: "A great work undertaken, a great enthusiasm undertaking it, and a great end kept steadily in view." It is self-evident that as a fundamental requisite to success in clinical research, pathology and practice in the art and science of medicine, enthusiasm stands foremost.

He whom we are here to memorialize was an enthusiast, a zealous enthusiast, a working enthusiast. Most of us, I dare say, learned of him by having come within the magical influence of his enthusiasm; felt the striking of the sympathetic chord and sought to know more of his work by being led on and on into the special field of his labor through the fascination of his originality. Few men in our profession have worked more diligently than he, and few have attained by their own persistent research his breadth of clinical culture; obtained step by step, pushing onward from one influential station to another and being adequate to the highest of them all.

Eskridge was an enthusiastic student of neurology to the last; he worked in his field until he knew the

Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

technic of his art. He acquired this art largely through his own powers of original research, his analytical discriminations and logical reasonings. He had no narrow views; hence no distortions to mar his conclusions. His freedom from bigotry, his catholicity of mind gave him unusual clinical foresight, and as a result remarkable powers in differentiation. Clinical culture was his, and the vast stored-up mass of impressions gleaned from his many years' work in this rich field, made him the safe counselor, the wise teacher, the able practitioner that he was. He was an indefatigable worker in spite of his physical infirmities—in fact, we may say that his infirmities seemed only to throw into bold relief his mental activity and give brilliancy to his work. It made him intense, absorbing in his work in order that his own sad experiences with disease might be drowned in the delights of intellectual life. Never was there an invalid who bore his maladies so cheerfully or who made so light of the terrible burden which he carried. To better be able to live with his invalidism, he was systematic in his rest and work, aiming to do the maximum with the least physical suffering. Even when within the clutches of his last illness he worked with that same enthusiasm as characterized his early efforts in Philadelphia. Of late years, when he foretold the coming of his end, he worked with singular persistence, doubtless to be perfect in his art—for his was a perfect art—that while he lived he could, at least, write of the specialty that he loved so well. Just here let it be said that this singular persistence of which I have just spoken, is shown in his plan of first mastering his specialty before he began to write for publication.

As a writer his ability was shown in the startling distinctness with which the picture of disease was penned; signs, symptoms and characteristics, diagnosis and differential diagnosis, stand out clearly by the aid of his precision in description. Few contemporaries have surpassed him in this feature of his work. His mind was logical; his thinking, precise and original; and it may be said of him, as was said of Alexander Hamilton, "He could do the thinking of his time."

Eskridge saw the birth of the art and science of neurology as a specialty, and as an American representative, wholly trained in this country (for he had no European experience) he was a leader—a leader of higher thought in the art of medicine; he disposed of many of the supposedly insuperable boundaries surrounding the nervous system and led the way for other workers to invade the mysterious home of mental and nervous activity. By reason of his continuous work he had no hours for emotions of despondency, for until the last work was the panacea for all of his afflictions.

It is not my purpose to follow his life outside of the domain of clinical medicine, for this has been done in a more fitting tribute by his fellows in Denver. To the profession who have attentively studied the literature of clinical medicine, there comes a feeling of personal bereavement in the loss of J. T. Eskridge; he was in touch with all of the great advances being made in medicine, and proved by his own observation the researches of others, and through his logical pen aided in the adoption or disapproval of their work. His own work was always scientific, always lucidly presented in his own rare literary style, and above all, it was never commonplace, because such contributions were never possible with him.

In conclusion, let me speak of his personality, the extra-professional characteristics, as delineated by Dr. Munn, of Denver, before the Denver and Arapahoe Medical Society, at the memorial meeting, Jan. 28, 1902. I

present extracts from Dr. Munn's appreciative and loving tribute to Dr. Eskridge because as a close friend and neighbor he gives, in more fitting language than can I, the nobility of character of that great man whom I know was to admire and to love, and, I may add, reverence.

"Those who have most work of their own can usually find more time to help others than can the idle, the selfish or the unemployed. It was wonderful how many men and women, how many diverse interests, and what different organizations claimed and received Dr. Eskridge's advice upon matters that were not professional. Matters of public and private interest were often submitted to his adjudication; measures of legislation sought his approval before their final passage; the courts were guided by his advice, and public officials deferred to him upon matters of policy. Those having personal knowledge of his stand in regard to many questions thus submitted to him, were impressed by the uprightness of soul and the impartial judgment with which he was gifted in such high degree. That such a man should die so untimely, called from his useful activities when he had reached an age that seemed to entitle him to some rest from the more pressing physical labors of life, yet when his mental and moral capacities might most profitably have been continuously exercised for the whole community, is, indeed, in the largest sense of the word, a public calamity."

"From the hospital and from the home, from the office and from the bedside, from the hovel and from the palace, from the people and the press, as well as from our own profession, the expressions of grief and bereavement at the passing of this man have been practically universal.

"At the bedside of the poor, as well as of the rich, we met him daily; and he was as kindly, as considerate, as conscientious, with the one as with the other.

"And if the hereafter holds for us further opportunities for activity and usefulness, as many of us devoutly believe, we know where we shall meet again this man who clothed the naked, fed the hungry and visited those who were sick or in prison.

"So, we say farewell to the frail body—and farewell to the great soul.

"The laurel and the bay are naught to him; they do but serve to make the lesson of his life and death more precious to us all."

ADDRESS ON AN EXHIBIT OF EARLY (PRIOR TO 1860) BRITISH AND AMERICAN OPHTHALMIC LITERATURE.*

CASEY A. WOOD, M.D.

CHICAGO.

At the outset let me say that the books, pamphlets, atlases, portraits and other illustrations of the early history of ophthalmology in this country and Great Britain are almost entirely derived from the private collections of the members of the committee. In addition to these we are equally indebted to the kindness of Dr. Dennett, librarian of the New York Eye and Ear Infirmary, for a copy of the first annual report, by-laws and other interesting matter relating to the oldest of our ophthalmic hospitals. Little or no notice is taken of the

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, H. V. Würdemann and J. A. Lippincott. The Exhibit was gathered by a Committee, appointed for the purpose, consisting of Casey A. Wood, Chicago, chairman; Harry Friedenwald, Baltimore; A. A. Hubbell, Buffalo, and A. R. Baker, Cleveland.

numerous monographs (about one-tenth of the whole) on cataract, since Dr. A. A. Hubbell, one of the members of our committee, will address you on that important subject. Particular attention is invited to the library and other relics in this exhibit of Dr. George Frick, which we are able to present through Dr. Harry Friedenwald, by the courtesy of the Medical and Chirurgical Faculty Library of Maryland. Dr. de Schweinitz has kindly loaned the first number of the Royal London Ophthalmic Hospital Reports and a copy of Brigg's *Ophthalmographia*, formerly in the library of the Duke of Bedford.

The exhibit of treatises and text-books, as well as of monographs on the eye and its diseases, will be found to contain, almost without exception, a copy of every work written in English or by an author of British or American birth between 1660 and 1860.

Just as a history of ophthalmology would not be complete—indeed, could not be written—without considering it as a part of the history of medicine, so it is impossible to divorce ophthalmic from general medical literature. The very form in which the fathers of ophthalmology cast their contributions to literature is that of the surgeons of their time. For this reason, if for no other, a full account of even that comparatively small portion of the world's ophthalmic literature which was written in English prior to 1860 could hardly be given, even in abstract, at this time and place. As you know, since the time of the ancient Egyptians attempts have been periodically and repeatedly made to set aside a class of so-called "oculists," but the better sense of the medical community has ever recognized the fact that ophthalmology is not an off-shoot from, but a veritable branch of the tree of medical knowledge, and that as such it can thrive only when in healthy union with the parent stem. I think, therefore, that it is in keeping with this idea of the universality of the medical art and somewhat to our credit that there never has been a distinctive "English" school of ophthalmology, although both Great Britain and America have not only contributed their store of discovery and learning to the common fund, but at one time (during the latter part of the eighteenth century) the former country probably furnished the most distinguished ophthalmologists in Europe.

The writings of modern Egyptologists, and in particular the editors of the Ebers papyrus, furnish us with proof of what had long been suspected, viz., that the Greek schools of medicine derived much of their knowledge of ocular therapeutics from the Egyptian oculists. As you know, medical and surgical specialism had its rise and its perfect fruition in the ancient Nile region. Not only were there exclusive "eye doctors," but the whole body was divided and subdivided among the profession to an extent undreamed of even in our day. From them, through the flourishing Greek schools of anatomy, the Roman oculists (*medici ocularii*) arose, to be in their turn followed by the Arabian ophthalmologists.

In the committee's exhibit will be found a well-preserved, medieval-Latin edition, printed and painted during the years 1489-91 by Boetius of Venice, of that renowned surgeon-oculist Avicenna,¹ or Abu Ali El Hosein Sina, born in Bokhara about A. D. 925. The

fifth book of the folio is entirely devoted to a description of the eye and its diseases. It was mainly from this source that the sixteenth century English surgeons drew their inspiration. Then, as now, it was considered proper in every general work on medicine to set aside at least a few chapters to a consideration of the ocular apparatus and its diseases. Time will permit me to refer to only one of these in the exhibit, an English edition, by Bartholomew Traheron (1543), of Johannes Vigo, that celebrated Italian surgeon who lived at the end of the fifteenth and beginning of the sixteenth century. "Thesemostexcellent workes of Chirurgerye," containing many references to Avicenna, appear to satisfy at least the editor, who, in the usual dedication to the patron, remarks, "whyche thyng if it shall plesse your ryghte godlye iudgemente, and suche as youe be, the barkynges, of other shall lytle trouble me."

Appended to the translation is a glossary for the student. From it we learn that a "cataracte" is a "slymy humour, growen togyther lyke yse, betwene the skynnes of the eyes, cornea and coniunctiua, cometh aboute the apple of the eye." Of collyria "there bene two kyndes thereof. One is liquide and the other is drye, and that they cal barbarously a Sief." Probably the latter reference is to the molded tablet, containing various ingredients, often bearing the name of the oculist imprinted on its surface, a solution of which when placed in water formed a sort of panacea for eye affections. Scotoma is defined as a disease "when darkenesse ryseth before the eyes and when all thynges seme to go round about. This diseases is (also) called vertigo, in latyne, of turnyng about, though some go about (we may imagine the contempt on the editor's face!) to make a follysh difference of scotoma and vertigo."

The first separate and complete treatise on the eye published (London, 1622) in the English language was written by Richard Banister, Mr. in Chyrurgery, Oculist and Practitioner in Physicke. If one compares this text-book with the larger and fully illustrated German work of Georg Bartisch, which, by the way, was published forty years before, we shall find that they both hold up to ridicule and contempt the deeds of those empirics that in their day, as in ours, prey on an ignorant and gullible public. Especially severe is Banister on those "Mountebanks" who fail to observe the well-known surgical rules, thus done into poetry:

Couch cataracts upon a day so faire,
That neither wind nor clouds disturb the Ayre,
When spring with simples fills the Earth's rich lap,
Or Autumne makes the tree put off his cap,
The Moone i' th' full, or in coniunction fly,
Or tracing Aries, or in Gemini.

"Great is the hurt," continues Banister, "that is done to the eyes, being peared with an instrument, in an open and airy place: for the aire getting into it, bringeth many euill accidents to the part, most commonly priuation of sight." Ignoring both these prose and poetic aphorisms the aforesaid charlatans, says he, "take their patients into open markets and there for vain glories sake, make them see, hurting the patient, only to make the people wonder at their rare skill. Some others make scaffolds, on purpose to execute their skill upon, as the French-men and Irish-man did in the Strand, making a trumpet to be blown before they went about their work." However, the punishment fitted the crime more promptly than it does in this day and generation. for "they were called before the company of the Chirurgions, being sharply reprooued, soon left the city and their abusive practice."

1. My attention has been called by Dr. Frederick P. Henry, Honorary Librarian of the Philadelphia College of Physicians, to a still older work—said by Hain to be the first edition of the first printed book on ophthalmology—now in the college library. It is entitled "De oculis eorumque aegritudinibus et curis." It was written by Beavenutus Grassus, and published at Ferrara, by Severanus, in 1474.

Banister early observed the harm that follows the application of acrid and astrigent agents to inflamed and irritable eyes, and frequently protests against such treatment. This is the more to his credit, since in his time disease was regarded as an entity, or at least as an excess of normal or diseased humor, to be driven or purged from the body. "A tender Eye," says he in his *Breviary*, "must have tender and gentle medicines. Sharpe and tart medicines doe exasperate. The white of an egge and woman's milke doeth moysten and cease paine. Metals are not to be used in the beginning (of an acute inflammation). . . . In ophthalmia medicines, they ought to be light and soft, without biting. Allam, copperise, Sandiver, Salt and such like, these used alone, or mixed with other powders or water made from them, must not be too sharpe. . . . I have often healed (eye diseases) with medicines that have no smarting quality at all, which cooleth, comforteth, and strengtheneth the eye. . . . Some in dressing of the Eyes will use some sharp water of allom, copperisse, or such like, three or four times in a forenoone, that so soone as the sharpness of one dressing is past, then beginneth another, and another, as though Rome was built in one day, or a disease in the eye were to be cured in one houre; whereas they do not consider, that much use of sharp medicines, either Collieries, water, powders, etc., do destroy the force of the sight: therefore beware of such hasty healers, who may well be called hasty hurters; for tender partes must be tenderly dealt withall, and that is safe dealing."

Strange it is that in the face of such experiences Anglo-Saxon surgeons continued for four subsequent centuries to inflict their zinc, silver and copper barbarities on the eyes of defenseless patients. Local applications of blue stone, silver nitrate, alum and other metallic substances, mixed with a heterogenous mass of vegetable excipients, gathered at the proper time of the month, with relation to the proper signs of the zodiac, constituted the ordinary treatment of eye affections. The general treatment may also be gathered from Banister's *Breviary*, of which the following is worth quoting: "When paine is exasperated, open a veyne largely in a full body, to prevent great danger. Fiery humours must be evacuated by cupping and horse leaches. Behind the eare is best. Use blistering to the necke. If the disease be stubborne, use visicatories to the top of the head and sutures. Purging the head with pilles, lest that part of the humour unsettled be driven into the Nerve opticts, and thereby cause grievous accidences, as staphiloma and such like, which I have often seene."

The early oculists had troubles like unto our own. "It is an usual custome," says Banister, "as soone as one complaineth of paine or grieve of the eyes, to have amongst twenty women, nineteene severall medicines told presently, little notice of the nature of the disease being taken, and the power of the medicines almost altogether unknowne. Within compasse of the womans Antidotary are roasted apples or crabs, while some of them licke the Eye with their tongues, some put a lowse into the eye, the juyce of goose dung, the white part of hen's dung."

A very fair description of the anatomy of the eye is given by Banister as well as by Wm. Briggs, whose monograph, "*Ophthalmographia, sive Oculi ejusque partium descriptio anatomica*," was published in Leyden in 1686, and is spoken of by Hirsch as one of the most important ophthalmic works of the seventeenth century. This small volume is illustrated by plates showing the

optic nerves joined at the chiasma, but with uncrossed fibers. In his *New Theory of Vision*, presented to the Royal Society, prefaced by a letter of approbation from Sir Isaac Newton, appears the statement, that while there is no crossing of the optic fibers yet single vision is obtained by the irritation of identical parts in the retina. Briggs was probably the first to declare this doctrine, as well as among the first to suggest that accommodation is brought about by changes in the lens.

A first edition of Newton's lectures is presented in our exhibit, and it is not necessary for me to remind you what an important rôle they play in our knowledge of physiologic optics. Query 15, at the end of Newton's "*Optics*," clearly states the hypothesis of the decussation of the optic fibers and their relation to human binocular vision, although it was, later, Walloston who showed just how this occurs.

Inaugural Dissertations and Disputations were not to the same extent a part of early British university life as they were and are on the continent. I have searched several hundreds of these sixteenth, seventeenth and eighteenth century theses in the hope of finding the name of an American graduate of Leyden, Göttingen or Utrecht, who presented a defense of some proposition pertaining to the eye, but have not found a single one, although I think there may be such, and would be glad to hear of any I may have overlooked. Even such students of English origin are few. Here is one, James Lidderdale, whose "*Disputatio Medica Inauguralis de Inflammatione Oculorum*" was presented, in pompous Latin, to the Leyden faculty in 1708, and dedicated, in the usual terms, to his relatives and friends. There are twenty-five pages, three of which are devoted to that serious disease, inflammation of the muscles of the eye! Inflammation of the optic nerve is exhaustively dismissed in half a page and affections of the lachrymal sac in about a third of a page. To my mind the most interesting portion of these two and three-hundred-year-old theses is the occasional appendix. In Dr. Lidderdale's case, five friends, one anonymous, one probably Scotch, one French, one German and one Italian, tell him, in various languages, what a loss the university will sustain and what a prize Scotland will gain when he once more puts foot on his native heath. The English contribution is too good to miss. You will notice that it takes the form of an acrostic:

To the Learned and Ingenious James Lidderdale, A.M., M.D.:

Ingenious Friend

All did admire to see,

Your parts, your learning, and your modestie
In that *De inflammatione oculi*.

Let the admiring croud to admire go on,
Its short of thy desert, when all they've done,
Doctor of Physic and Philosophie;
Deservedly enrol'd M.A., M.D.

Each Faculty you know; to say how wel,
Requires (if possible) those that excel,
Dryden, or Waller, Cowley, Philomel,
Accept my wish, tho in an homely stile
Let still successe on your endeavors smile
And be the fam'd Physician of Great Britain's isle.

The dawn of the eighteenth century saw the rise of many celebrated surgeon-oculists, the best known being Thomas Woolhouse and John Taylor, his pupil. The career of each closely resembled that of the other. Both acquired a continental reputation, though not always of the highest character; both were appointed surgeon-oculist to almost all the courts of Europe; both were

well educated, skilled operators, publishers of many works on the eye in English, French, German, Italian, etc., and both received numerous degrees from the universities of the continent and honors, presents and decorations from emperors, kings, princes and other potentates. Both eventually settled in Paris, where they attracted many students and patients.

From the middle of the seventeenth to the end of the eighteenth century frequent reference is found in Forest, Thomas Hope, Banister and others to the practice indulged in by certain oculists of going about from town to town practicing their art. Although there could not be any objection to a surgeon's traveling about in the pursuit of knowledge and for the purpose of acquiring a wider reputation, yet the circumstances surrounding these journeys, the assumption of superior knowledge, particularly of operative skill, the ostentatious display of a retinue of servants, the wearing of rare jewels, fine clothing, decorations, etc., the undisguised attempt to displace the regular surgeons at the various courts, the publication of long lists of rewards for service and accounts of cures in the families of reigning princes or members of the nobility—these brought into disrepute all peripatetic oculists of whatever degree. Moreover, the success of such men of the Chevalier Taylor type bred a large number of humble and unskilled imitators, who, without any real knowledge of eye diseases or any skill in surgery, went through the country extorting money from the ignorant, couching cataracts and selling panaceas for eye diseases, with the market place or cross roads for their offices and musical instruments to herald their approach. Forest thus speaks of those that about this time spread over Holland and invaded England: "*Sunt enim multi oculistae qui per urbes vagantur et fraudulentè agunt, pecuniarum extorquentes ab aegrotantibus multaque promittentes quae tenere non valent.*"

Woolhouse was the author of a number of works, most of them containing attacks on Maitre Jan, Heister and others. This author was undoubtedly the first to suggest the possibility of making an artificial pupil, an operation later carried out by one of his assistants, Cheselden. Both French and German editions of his interesting treatises—1711 and 1715—on the various operations on the eye performed in his day, as well as a description of the instruments employed, are still extant. Taylor, a student with Haller under Boerhaave, was the more able, more brilliant and more scientific of the two, and it is now admitted that if he did not actually perform the operation, he claimed to have cured strabismus by a myotomy of the recti muscles, so that we must assign to him the honor of being the first to advocate the measure itself. He also described systematically over 240 eye diseases.

It must not be forgotten that the early English surgeons vied with one another in discovering additions to the known and published list of diseases, and thus we find, through the decades, a sort of numerical competition which was reflected in the titles of their treatises and text-books.

Wm. Cheselden, who made the first artificial pupil, was born in 1688, and was famous as an anatomist. He was one of the surgeons to St. Thomas' Hospital. Samuel Sharp, born in 1778, was a pupil of Cheselden and one of those who performed a modified Daviel extraction operation. We must not forget Alexander Monro, (1697-1767), Scotch ophthalmic surgeon, famous, as was Jonathan Wathen, for his studies of the lachrymal apparatus and its diseases.

In 1759 William Porterfield published, in two volumes, his masterly "Treatise on the Eye, the Manner and Phenomena of Vision," chiefly a work on physiologic optics that, in conjunction with the writings of Isaac Newton and Thomas Young, forms an enduring monument to British ophthalmology. You all remember the letter in which our Dr Knapp mentions the tribute paid by Helmholtz to Young—that when, in working out a problem in optics, an apparent contradiction of a statement made by the English mathematician was encountered it uniformly happened that Young was correct. Two English editions of Young's works have been published; the first, his lectures in two large volumes (1807), and the second in three volumes by Peacock, 1855. Of these the earlier edition is to be preferred.

Wm. Rowley, born in 1743, was even better known for his ophthalmic writings. His "Treatise on 118 Principal Diseases of the Eye, in which are communicated several new discoveries Relative to the Cure of Defects in Vision, with Original Prescriptions," dated 1790, is well worthy of perusal. On page 358 is printed an extract from a letter written by one Dr. Benjamin Franklin to "My worthy friend, George Whately, Esq., Treasurer to the Foundling Hospital."

By Mr. X. saying that my double spectacles can only serve particular eyes I doubt he has not been rightly informed of their construction. I imagine it will be found pretty generally true, that the same convexity of glass through which a man sees clearest and best, at the distance proper for reading, is not the best for greater distances; I, therefore, had formerly two pairs of spectacles, which I shifted occasionally, as in traveling I sometimes read, and often wanted to regard the prospects. Finding the change troublesome, and not always sufficiently ready, I had the glasses cut, and half of each of each kind associated in the same circle. By this means, as I wear my spectacles constantly, I have only to move my eyes up or down, the proper glasses being always ready. This I find more particularly convenient since my being in France, the glasses that serve me best at table to see what I eat, not being the best to see the faces of those on the other side of the table who speak to me; and when one's ears are not well accustomed to the sound of a language, a sight of the movements of the features of him that speaks, helps to explain; so that I understand French better by the help of my spectacles.

"I have ordered," adds Rowley, "some of these spectacles to be made by Mr. Bemfleet in Saville Passage, near my house, and have recommended their trial to several people, by whom they are highly approved."

The latter end of the eighteenth century saw the fruition of the art of engraving on steel and copper—now lost or almost lost to us—and Rowley's treatise is well illustrated by drawings reproduced in this satisfactory manner.

There is some connection—sociologic or religious—between the rather sudden disappearance of a belief in witchcraft and the discarding of certain superstitions in medicine, not to be explained altogether by the dissemination of scientific truth. John Fiske has drawn our attention to this curious fact in the matter of the belief in witches in New England and it forces itself on us in a review of ophthalmic writings. In George Bartisch's treatise not only is witchcraft of the eye acknowledged and its symptoms minutely described, but the charms to be worn and the prayers and other means necessary for the prevention of the diseases and its treatment are duly set forth. Comparatively little space is devoted to matters of this character in English publications. Rowley, for example, pleads for a rational treatment of the king's evil, and his work is almost as free of dogmatic statements concerning things

supernatural as is any work written in our own generation.

John Ware, who died as late as 1816, about this time wrote voluminous works on various ophthalmic subjects, most of them published by his son in two volumes, 1818.

Two features particularly distinguish eighteenth century therapeutic literature, viz., long, complicated prescriptions and the search for cure-alls. Examples of these are furnished, for example, by Sir Hans Sloane—him of the Museum in Lincoln's Inn Fields—physician to His Majesty, etc., in a pamphlet, dated 1745, and entitled "An Account of a most Efficacious Medicine for soreness, weakness and several other distempers of the Eye." Thompson's eye water and Petit's eye salve of our day, with a number of minor contestants, now hold the field of popular favor, but the idea of the panacea is the same.

As we approach the beginning of the nineteenth century the first writing on eye diseases by an American of which I can find any account appeared, according to Harry Friedenwald, in the *Medical Repository*, Volume VII, page 28. It is entitled "An account of a case of Fistula Lachrymalis, with reflections on the different modes of operating in that disease." The author is Dr. Pierre Chatard, who settled in Baltimore in 1797, but who does not appear to have made a specialty of eye diseases. From this time forth comparatively frequent and important additions were made to ophthalmic literature, not only in Great Britain, but in America. The British and French ophthalmologists were then the best known in the medical world, although they were soon to be rivaled and eclipsed by the brilliant labors of Barth, Beer, Schmidt and other German surgeons. I have time to mention only a few of the more important.

Sir William Adams wrote during the first two decades of the last century. Following him were many others, authors of complete treatises of goodly proportions, which, as a rule, were well illustrated and especially replete with reliable descriptions of diseases of the eye. I wish to mention particularly J. C. Saunders, the first edition of whose celebrated treatise was published about 1811; G. J. Guthrie's "Lectures on the Operative Surgery of the Eye," which were published in London, 1823; John Vetch, "A Practical Treatise," London, 1820; A. Watson's "Compendium," Edinburgh, 1828; Wm. Lawrence, "A Treatise on Diseases of the Eye," 1833; Benjamin Travers, a deservedly popular text-book, with several editions, first issued in 1820; Middlemore's treatise, two volumes, published in 1835; Morgan's volume of lectures in 1839; F. Tyrell's two-volume treatise in 1840; Walker's "Vade-Mecum," in 1843; Haynes Walton, and Wharton Jones. Last, but by no means least, we note the appearance of the first edition of the greatest of all the British text-books, by Wm. Mackenzie, in 1830.

The works of most of these ophthalmic writers—and I have by no means given a complete list of them—ran through several editions, and a few of them were translated into foreign languages. The treatise of Jno. Cunningham Saunders is of especial interest to us because it was the first complete work on disease of the eye published in America, having issued from the press of Benj. Warner at Philadelphia in 1821. It was very appropriately dedicated to his teachers of anatomy (of which Sir Astley Cooper was one) and to the officers of the London Infirmary for Curing Diseases of the Eye, whose legitimate descendant is the Royal London Ophthalmic Hospital, better known as Moorefields. Saunders was undoubtedly the first to propose a special hospital for eye diseases, and was the founder of this one, which was

opened for the reception of patients in March, 1805, although the Royal Westminster Infirmary was formed and established a few months previously. Saunders was not fated to enjoy, for any length of time, the practice of the house he had built. Symptoms of organic disease of the brain developed in the beginning of 1809. Although the disease interfered greatly with his work, he refused to take the needed rest from his arduous labors. The description of the eye symptoms in his case is interesting, one might say almost pathetic, viewed from the standpoint of our time. "He was affected with an imperfect amaurosis of the right eye. The eye was carefully examined, but the pupil was found to be of its proper size and figure—objects, besides being obscured, were diminished in size and deranged in position, the accurate distinction of colors was lost." After nearly a year of suffering he died in January, 1810. The first edition, most of which was written while barely able to hold pen in hand, was edited by his friend J. R. Farre, illustrated by colored engravings and published at the expense of the infirmary for the benefit of his widow.

(To be continued.)

A MODIFIED FORM OF TEST-CARD AND TEST-LETTER.*

ELMER G. STARR, M.D.
BUFFALO, N. Y.

The importance of painstaking care and accuracy in determining the refraction of the eye is well understood by the ophthalmologist of to-day. Indeed, in America, those in the front rank in every department of medicine recognize the great value, for the relief of many disturbing conditions, of accurately correcting refractive errors. Any suggestions which may render results more certain are of value, and the careful ophthalmologist will spare no effort to reach a decision as nearly correct as possible, well knowing that what appears to be a slight error in the measurement of any eye's refraction may render valueless the work of making the measurement, and cause a failure of his attempt to relieve a patient of some distressing condition.

The question of illumination, the position of test types with reference to patient and light, and even the arrangement of the case of test lenses, all are worthy of attention. Since, with few exceptions, our final determination of the refraction is made with test lenses and test types or letters, these occupy the place of chief importance in this work. No great change, in the way of improvement, has been made in test-letters since the classical work of Snellen in 1862. He investigated the problem thoroughly and gave us the geometric letter of definite size and proportion of line. For general use the letter must still be the best form of test-object, as it best serves to indicate the accuracy of the patient's judgment as shown by the correctness with which he names the letters. Much of the difficulty experienced, and the uncertainty of results reached with this, the final method, depends upon lack of careful and accurate observation on the part of the patient; and much of the "refractor's" success depends upon the aid which he gives the patient, in educating him to observe nicely;

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, H. V. Würdemann and J. A. Lippincott.

for few persons observe comprehensively when subjected for the first time to a test of this kind.

That there are objections to the test card, as ordinarily employed, I have long been convinced. One of the most serious of these is that it quickly produces retinal fatigue, a result which is caused by the glare of light reflected from the surface of its white background. This is a very important factor in causing fatigue of the eye and lessening its sensitiveness to slight changes in distinctness of outline of the small test letters. Dr. Gould of Philadelphia has devised a card which is free from this objection, by making the ground black and the letters white. In this form of test card there is, however, an objection and that is the effect of irradiation seen about the letters, an effect observed when a small white body is viewed against a large dark background. The effect of irradiation is to increase the apparent size of the small object and at the same time to lessen the sharpness of its outline. Except in intense illumination, the effect of irradiation is not observed with a small dark body on a light ground. Another imperfection in the ordinary test-card is shown in the fact that with nearly all eyes, save those having very acute vision, the decision regarding the glass which gives sharpest outline to the letters is often uncertain within $1/4$ d., and in low amounts of astigmatism the position of the axis is uncertain within an arc of 5 to 10 degrees.

While it is evident to any one at all familiar with the subject, that no device can make the task of measuring the refraction a simple or easy one, yet I think that some of the difficulties encountered may be eliminated or lessened. As the result of an attempt to avoid some of the objections to the ordinary form, I have devised a series of letters which I here show. Some of the letters, it will be observed, are in color on a ground of another color, while others are built up of two colors and are on a ground of neutral color. The two colors used are, in both instances, yellow and blue; colors which are complementary. The reason for using these two colors will appear later on. By using a background of color, the glare of light and retinal fatigue resulting therefrom is lessened, and we are enabled to take advantage of, and utilize, the phenomena of contrast of colors in such a way that the lessened illumination is not a disadvantage as would be the case with a test-card of black letters on a white ground. It is well known that a color can be materially changed in brilliancy and saturation by altering the color which lies adjacent to it. Without entering into a detailed examination of the laws which govern the result, it is sufficient to say that when a colored object, such as a letter, is seen on a ground of complementary color, the color of the letter is strengthened and made more saturated and brilliant. That this must be so is evident when we reflect that the after-image of a colored object is always in complementary color. This phenomena is most noticeable when two colors are contrasted successively in the following manner: A small square of black paper is placed on a sheet of yellow paper (any other color might be used) and the attention is directed to the edge of the former. If now the black square be suddenly removed the observer sees in place of it a luminous spot which in this case will be yellow, but what is remarkable is the fact that this yellow image or ghost will be more intense and saturated in color than the rest of the ground. The rest of the yellow paper will appear as if gray or white had been mixed with it. This experiment succeeds with paper of any bright color, and Helmholtz has shown that the same effects are obtained with the use of pure spectrum

colors. If instead of employing a black square we take one which has a color complementary to that of the ground, in this case blue, the result is much the same as before, except that the yellow ghost is now still more intense and brilliant in color.

These phenomena are cases of what is called successive contrast, because we look in succession from one surface to another. When colored surfaces are placed in juxtaposition and viewed in the usual way, successive contrast still plays an important part, and the appearance of the colors is still modified according to its laws; for although we attempt to confine our attention to only one of the colored surfaces, the eye involuntarily wanders to the other; for absolutely fixed vision is quite opposed to our common habit, if, indeed, it be not an impossibility.

Yellow, being the most luminous color in the spectrum, is selected for the ground and blue, its complementary, the color for the letter. Not only is the blue letter more sharply defined, by contrast, but the yellow field also gains in brilliancy, in the same way. By filling in much of the field with black, leaving the background of yellow only sufficiently large to give the proper effect of contrast, we still further diminish the amount of harmful light which can reach the eye. In practice it is found best to have the yellow ground for each letter about three times the diameter of the letter, in the small letters. All else may be black. By this means we still further increase the brilliancy and contrast of the yellow and blue. The letters are of the proportions of those generally used. In practice I find it advantageous to employ letters of a slightly smaller angle than $5'$ in measuring the refraction, as in this work the aim should be to get the best possible vision—not to be content with $20/20$, or what is commonly designated "normal vision."

Referring now to the letter built up in two colors, I will say that the object aimed at in thus making a compound letter is to produce a more sensitive test object than we have in the solid letter; something which will make more evident any lack of perfect focusing of the retinal image and, therefore, make it easier for the patient to be accurate in his decisions regarding the effect of different test lenses. The letters are made up of two colors which are complementary, one-half of the letter being blue, the other half yellow. The colors are laid longitudinally on each line of the letter, and the background is gray.

A mixture of complementary colors produces gray, and a letter which is built up, in this way, of complementary colors, will look gray to an eye which, through lack of proper focusing, receives the mixed colors on its retina. If, now, the letter is on a gray background as described, the eye can not distinguish the outlines of the letter, and with proper adjustment of colors the letter will be quite invisible. A slight overlapping of the colors, from imperfect focusing, gives the letter a gray appearance, like its ground, and a lens which corrects this overlapping and brings each color sharply into focus produces a much greater contrast than is the case with a black solid letter on a white ground.

Theoretically, any two complementary colors might be used, but practically, I find blue and yellow the most satisfactory, as they each offer the greatest contrast with gray and allow of a smaller letter being used than is the case with any other two complementary colors. It is important that the blue and yellow of which the compound letters are built up be true complementary colors as otherwise a pure gray does not result from their mixture. The proper colors must be determined by actual test with the rotating disc of Maxwell. The colors here used are, for the blue, cobalt blue mixed with a weak solution of gum arabic, just sufficient gum being used to bind the color to the paper; and for the yellow, a thin wash of gamboge mixed with water. These colors when mixed by a rotating disc produce a gray known by paper dealers as platinum gray or platina. Red and green, when mixed, produce a very light gray, but they offer a poorer contrast, separately, with gray, so that the retinal image must be increased in size by increasing the size of the letter to such an extent as to destroy its value as a test for visual acuity, and to greatly lessen its value for purposes of refraction. A letter made up of yellow and blue must be larger, but not greatly so, than a letter of solid color, to still be visible at the normal distance and when properly made is a very sensitive test object. In practice, I find it advantageous to combine the two forms of test-objects here described. The solid letter is the better index of visual acuity and the bi-colored letter is the more sensitive test-object for use in measuring the refraction.

DISCUSSION.

DR. GEORGE M. GOULD, Philadelphia—Speaking of his very ingenious device, Dr. Starr alludes to a test card which I have used for several years, which is black with white letters, and finds that the effects of irradiation trouble him. I illuminate my cards very brightly, and place them at such angle that there is no sheen. I have nothing to complain of as to the irradiation. The card is devised according to the physiologic principles of the eye, the black being a non-stimulant of the retina, does not fatigue the eye, especially when the accommodation is paralyzed. So with this card I often put down normal vision as 20/15 and very often patients can read 20/10. I can read 20/10 easily with it, because the retina acts physiologically. I think Dr. Starr's ingenious device deserves further consideration, but it seems to me that the greatest contrast between stimulation and non-stimulation must be between black and white.

DR. B. A. RANDALL, Philadelphia—It seems to me that the prime conception as to test-letters is often lost sight of, and this is partly to be laid at Snellen's door, since in making the 5-minute letter he did not make more plain that he was testing the vision with its parts and interspaces of 1 minute. Therefore, a letter, whether of 5-minute angle or less, is not a test if its parts are not such as to make the interspaces 1 minute. In using the simple letters, as in the card of Dr. Gould and Dr. Starr, everyone finds that 20/20 is not the normal, but that lower lines can be read.

The matter of irradiation is a factor in the construction, as noted 20 years ago by Giraud-Teulon and Javal, and the doing away with this is of importance in our work and is well secured in a great many of the letters in general use, the best being that of John Green of St. Louis, where the terminal additions are half-blocks. The irradiation which is reduced by this can be made almost nothing by having the card, not the bright yellow, but merely a cream color or India tint. To those of you who are going to construct letters, I would say do not make the common error as to the size of your letters, for 99 out of 100 make the letter according to the tangent of the angle, while twice the tangent of one-half the angle is the proper thing; and see that each part and interspace subtends 1 minute. We can not be too precise in dealing with this subject.

DR. E. J. GARDINER, Chicago—I would like to ask Dr. Starr if the irradiation that troubles him may not be due to uncorrected astigmatism?

DR. STARR, in closing—In reply to Dr. Gardiner, it is certainly worse in such a condition, but I get it at all times with my own eyes. In regard to the form of the letters I can hardly agree with Dr. Randall. I prefer to test by means of the lines, rather than by the interspaces of the letters, and to use a line subtending a smaller angle than 1 minute. I want the patient to be familiar with the letter under observation, and to carefully observe which lens gives the sharpest outline of the letter.

METASTATIC SARCOMA OF THE CHOROID.*

MEYER WIENER, M.D.

ST. LOUIS.

Next to glioma of the retina primary sarcoma of the choroid is the most frequent intra-ocular growth. Metastatic, on the contrary, is extremely rare and has only been authentically reported by Shieess-Gemusens, Pflüger and De Schweinitz. In Norris and Oliver's System of Diseases of the Eye (1898), Hill Griffith, in his article on sarcoma of the choroid says: "Sarcoma of the choroid is always primary, always single and generally more or less deeply pigmented; it never affects both eyes." We are all familiar with the saying of Virchow that in those organs which show a special disposition to nurture new growths, metastatic foci are seldom seen. Thos. Axenfeld, in a review of "Tumors of the Eye," published in 1897, says: "We know of only two positive cases of metastatic uveal sarcoma; those of Pflüger and Shieess-Gemusens and Roth." In Pflüger's case one eye became blind while in the other a tumor formed in the anterior chamber, with episcleral nodules following an enlargement of a nevus in the region of the right parotid. A microscopic examination was not made. Uthoff seems to think these two cases were metastatic carcinoma. A. V. Meiggs and Dr. de Schweinitz report a case of "Double-sided, flat choroidal tumor on posterior pole in a case of sarcoma of the anterior mediastinum" as follows: "A 21-year-old laborer had tumor of anterior mediastinum (which is described as round-celled sarcoma), numerous metastatic nodules in the brain, especially on base; marked tumor thickening of optic nerve as well as motor oculi and orbital muscles. Double-sided independent tumor of choroid." This case, according to Axenfeld, seems to correspond with one of three cases of metastatic "malignant lymphoma," which began also in the mediastinum but in these three cases there were no intra-ocular growths. Cases have been reported by Mitvalski, Eschling, Uthoff, Kamoki, Schulz and others, of metastatic carcinoma of the choroid. In not a single text-book of ophthalmology that I possess is metastatic sarcoma of the choroid even mentioned.

In the case which I have to report both eyes were affected, and I procured one of them. The eye was removed from behind, the cornea, lens and ciliary body being left in the orbit. Only the posterior half of the globe was removed. The retina was completely detached, during the removal most likely, as it seemed to be of normal microscopic appearance when stretched out.

In this eye I find sarcomatous patches which are visible on macroscopic examination, and all varying in general appearance as to size, color, etc. The largest and most prominent lies just below the optic nerve entrance and apparently just including it. This patch is of oval

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, H. V. Würdemann and J. A. Lipplincott.

shape, $8\frac{1}{2}$ mm. long in vertical diameter by 6 mm. wide in the horizontal; has white, lustrous, smooth appearance, clear and distinct outline and raised above surface about 0.5 mm. Immediately above this is a circular patch 3 mm. in diameter of the same appearance as the former in the center, but pigmented toward the circumference. Three mm. to the temporal side of this last patch is an irregular, ragged rectangular-shaped one, 6.0 mm. long by 4 mm. wide, of reddish color (probably from choroidal pigment), in some places darker than in others. This patch, unlike the others, has an uneven, broken surface, elevated in some places to about 1 mm. Two more sarcomatous areas are visible, one just below the macula lutea, the other just to the temporal side. Both of these are whitish with here and there deeply pigmented spots. Optic nerve seems to be somewhat swollen behind its entrance.

Microscopically, these patches are seen to be chiefly of the small round-celled type, with some spindle cells; growth is traversed by many blood vessels and channels. The growth is located chiefly in the tunica vasculosa, involving also, where it broadens out, the chorio-capularis. Here there seems to be a special cell proliferation or accumulation from the lamina vitrea. Surrounding each patch are more than the average number of vessels, filled with blood, and some of these attaining large size. Scattered throughout the growth some choroidal pigment can be seen having undergone degeneration or change of shape in many instances. Optic nerve is swollen and somewhat thickened at the entrance to the globe, but there is no infiltration of sarcoma cells.

I am indebted to Dr. Willard Bartlett for the following postmortem report:

City Hospital, April 26, 1900. Permit No. 500, Div. 5. Name: B. C. Admitted April 18, 7:10 a. m. Died April 25, 6:30 p. m. Age 26. Nativity Vermont. Cadaver of a tall man, of slender, bony frame, poorly muscled with scant subcutaneous tissue.

Skin.—Skin is of a pale, grayish color. Beneath the skin of the scalp, face, chest, abdomen, upper extremities, inguinal and femoral regions, back and buttocks, are nodules over which the skin is movable and intact. The nodules are also movable on their bases. They vary in size from a buckshot to a hickory nut and are in consistency reasonably firm. On the left buttock is one pedunculated prominence the size of a large walnut, its convex surface showing a loss of substance. On the posterior surface of the sternum are various nodes varying in size from a buckshot to that of a hickory nut. Following the course of lymphatics in anterior mediastinum are similar nodes which are of a light-gray color.

Pleuræ.—The anterior and posterior aspects of both pleuræ are studded with nodules of same shape and color as those before mentioned. The pleuræ are non-adhesive and sac contains no unusual contents.

Heart.—On opening the pericardium there is seen a similar collection of nodules on visceral surface. The heart corresponds in size to fist of the individual and the apex is formed by the left ventricle. Nodules are seen beneath endocardium.

Lungs.—Fairly voluminous. Right lung is retracted. On section the left lung, upper lobe, is seen to be the seat of a decided interstitial change, there being small amount of air-containing tissue; also areas of miliary pneumonia and hepatization. The lower lobe is thickly set with nodules.

Pharynx and Esophagus.—Mucous membrane coated with a mucopurulent mass. The retropharyngeal lymph spaces show nodules in size from a buckshot to that of a hickory nut. The tongue one inch from tip presents on right side a thickened area the size of little finger nail.

Larynx and Trachea.—Have their mucous membranes intact and covered with mucopurulent mass. The peribronchial nodes are decidedly enlarged, one presenting a node when split the size of a large hickory nut.

Spleen.—Size $16 \times 11 \times 4\frac{1}{2}$ cm. Presents on convex surface several nodules of various sizes and within parenchyma are felt numerous others. On cut section are seen projecting from the softened, grayish-red splenic pulp, nodules varying in size from a buckshot to an English walnut; many of these depressed and red at center. The edges in all instances yellow. Trabeculæ and follicles not seen.

Suprarenal Capsules.—Left slightly enlarged: Right measures $6 \times 6\frac{1}{2} \times 2\frac{1}{2}$ cm.

Kidneys.—(Left.) Ureter and vessels as usual. Fatty capsule contains numerous nodules of varying sizes and but little fat. Kidney itself is in size $13\frac{1}{2} \times 7\frac{1}{2} \times 4\frac{1}{2}$ cm. On cut section as well as on outer surface are immense nodes varying in size from a small shot to a hickory nut, many with reddish but slightly depressed center. Cortex wide and in part slightly clouded. Medullæ singularly free from growths, pelvis, however, presenting nodules. (Right kidney.) Ureter and vessels as usual. Size slightly less than that of left side and involved in same manner.

Liver.—Size, lateral 26; vertical 19; antero-posterior 7 cm. Outer surface in general smooth. Color, intense reddish-brown. Presents on anterior surface three large nodules, one of which has a reddish depressed center. On cut section is seen but one nodule. The central veins are decidedly wide and depressed. Organ contains a large amount of blood. Consistency firm.

Mesenteric Lymphatic Nodes.—In part involved, some nodules being as large as a small hickory nut. Grayish-red in color and of moderate consistency.

Stomach.—Interior presents mucous membrane swollen, clouded and bile stained; and, in addition, numerous ulcerated patches varying in size from a split pea to that of a dime, extending $\frac{1}{2}$ cm. above surface, soft and ulcerated. There are felt in stomach wall numerous nodules about the size of a buckshot.

Intestines.—(Small.) Nodules of varying sizes, a few of which have ulcerated into lumen of gut; in addition, a few ulcerated patches, the size of a dime, apparently tuberculous. On the opposing serosa is a miliary granulomata. There, in addition, beneath the mucosa and serosa are grayish nodules the size of a hazel nut, a few of which are broken down into the intestine. (Large.) Aside from moderate filling of submucosal veins, no irregularities. The rectum is immensely distended. Breadth 15 cm. Mucous membrane decidedly pigmented, otherwise as usual.

Pancreas.—Size $13 \times 4 \times \frac{1}{2}$ cm. Its tail is thickened and shows marks of adhesions to surrounding structures. On section are seen similar nodules as those described disseminated throughout entire organ.

Bladder.—Mucous membrane intact; wall of usual thickness, and cavity slightly dilated. At the right of median line and at $\frac{1}{2}$ cm. behind the verum montanum is one nodule lifting the mucous membrane, the same the size of a small hazel nut.

Brain.—Base of brain is, as far as vessels are concerned, uninvolved. Nerve trunks are as usual. The cortex is marked by circumscribed hemorrhagic areas varying in size from a split pea to a ten-cent piece. Pia mater is as usual. The cortical surface: $\frac{1}{2}$ cm. from corpus collosum, in opening lateral ventricle, is seen to be the seat of a hematoma the size of a hazel nut. The ventricles contain the usual amount of the usual fluid and are not dilated. The fourth ventricle and aqueduct of Sylvius are, as regards contents and size, as usual. On making the horizontal grand incision on the right side, there is seen immediately beneath the corpus striatum in the temperosphenoidal lobe, a hematoma the blood of which is clotted and about the size of an English walnut. In the cortical portion of the frontal lobe, 1 cm. beneath the surface, is a hematoma the size of a hazel nut, contents fluid and brownish-red in color.

Cerebellum.—Macroscopically, as usual. Pons and medulla show no evidence of change.

Arteries.—On opening internal mammary artery it is seen that the nodules that lay in close proximity do not invade the lumen of the vessels. The lumen of aorta is narrow.

The origin of the dorsal arteries is irregular. Vessel wall is thin and highly elastic, the intima showing slight fatty metamorphosis.

Groin.—The mass in left inguinal region is as big as a turkey egg, consisting of irregular nodes, black in color, and rests on the Sartorius muscle, Poupart's ligament and the structures between forming the floor of Scarpa's triangle. The branches of lumbar plexus which pass under Poupart's ligament are uninvolved in greater part by the growth.

Spinal Cord.—Lower portion, dorsal region, are found, lying posterior to cord on dura mater, several flattened, rounded tumors, varying in size from a buckshot to a medium-sized hazel nut.

DISCUSSION.

DR. EDWARD JACKSON, Denver—I would like to ask Dr. Wiener if he got the history at all.

DR. WIENER—I did not get any history from the patient and did not see the case until the patient was dead. I only reported the case because of its rarity. The growth probably started in the mediastinum and it seems to correspond in many ways with the case reported by Dr. de Schweinitz.

ONE THOUSAND PERSONALLY CONDUCTED CASES OF ETHYL CHLORID NARCOSIS.*

MARTIN W. WARE, M.D.

SURGEON TO THE GOOD SAMARITAN DISPENSARY,
 NEW YORK CITY.

After an anesthetic has been demonstrated to be effective, the next absorbing and vital question is its safety. On this score the brute force alone of numbers is telling, and I hope, therefore, in this narrative, to carry conviction in this direction on the basis of one thousand personally conducted narcoses with ethyl chlorid, and some collected statistics. These thousand narcoses were all conducted with ethyl chlorid sold under the trade name of "Kelene" and a mask of my own devising, described in previous communications.¹ For the present I must insist on the use of the above variety of ethyl chlorid, since other preparations marketed in this country, ordinarily intended for local anesthesia by freezing, are impure, containing methyl chlorid to facilitate evaporation. Furthermore, it happens that the above mentioned preparation of ethyl chlorid is the only one thus far provided with a suitable automatic cutoff to control the escape of ethyl chlorid, which issues from the vial in a very large stream. A number of masks described in foreign literature are not only ineffective but very costly. This simple, inexpensive device covers all requirements. The rubber cone makes an air-tight space about the nose and mouth; on to the gauze surface the ethyl chlorid is sprayed, the stream being released intermittently, from a distance of six to eight inches. Other details have been described in previous articles, and I would, therefore, limit my remarks to answering such criticisms as have come to my notice.

Does success attend its use in every instance? No more nor less than can be said of the other anesthetics. We estimate that in 95 per cent. an absolutely satisfactory anesthesia was obtained. This anesthesia sets in

promptly, at intervals of a few seconds in infants to three minutes in adults, and the awakening is equally as prompt. During the narcosis the color is natural and there is tolerable relaxation of the muscles. The giving of the anesthetic is controlled by the same criteria that hold good for other anesthetics. Mention is made in one of my previous writings of a layer of "hoar frost," resulting from the combination of the vapor of the breath with the ethyl chlorid, which forms on the gauze. I have now learned to regard this rather as a favorable than a deterrent factor, provided the frost be not allowed to form in too thick a layer so as to intercept all access of air. This "hoar frost" constitutes a storage depot for much of the ethyl chlorid and thereby facilitates narcosis. If a mask so saturated with this layer of "hoar frost" be applied to one's own face as for purposes of inhalation; no chilling of the inspired air will be perceptible, but a decided odor of a very pleasant nature is appreciated, and if the application of the mask be persisted in a little longer a sense of dizziness overcomes one. No untoward experience has resulted from the inspiration of air chilled in its passage over the frost, since the vapor of ethyl chlorid is dispelled, expanded and warmed in the pharynx before being taken up in the lungs.

Most of the observers advise spraying the ethyl chlorid in the various devices employed, in great quantity at once. This is unnecessary and likely to be dangerous. Perfect safety and great economy are insured by spraying intermittently. To guard against an interruption of the anesthesia by temporary occlusion of the capillary opening in the vial, an additional tube should be kept at hand. The stream must at all times issue in full force, since a dribbling stream will be attended by failure.

Children and young adults constituted about 75 per cent. of the instances in which this anesthetic was applied, and it has been remarked that the brilliant results witnessed were obtainable with all anesthetics in children. This is not the case. In the first place, the onset of the anesthesia is more rapid than with the other agents, and then the hasty awakening and remaining so from an immediately preceding profound narcosis is peculiar to none of the other anesthetics. For ambulatory practice this feature is only rivaled by laughing gas. Relaxation of all muscles is manifested in the state of profound narcosis; it is seen at its best up to adolescence, thereafter more or less rigidity is at times encountered. This is more so apt to follow when the reflexes are heightened in the inflammatory conditions demanding operation. In old age this anesthetic again operates as in infants, thus a successful reduction of a dislocation of the shoulder of long standing was effected thereby in a woman 80 years of age. To overcome the objectionable rigidity, I have in a number of instances administered morphin sulphate, gr. 1/4, as a preliminary. In proportion as the patient is addicted to alcohol, ethyl chlorid will cease to act favorably, wherefore in outspoken alcoholics a preliminary use of morphin hypodermically will insure a good anesthesia. Adults can be sufficiently anesthetized to do any minor operation of well-defined limits, but often at the expense of ethyl chlorid in large quantities.

Up to this point laughing gas is a strong competitor, but as cyanosis is never encountered with ethyl chlorid the latter takes the lead, also outstripping nitrous oxid on the score of portability and the cost of application. As the field of ethyl chlorid is only for minor operations, it must be pitted against nitrous oxid. The latter

1. Medical Record, April 6, 1901; Medical News, Aug. 3, 1901.

has the greatest record statistically for safety, its death rate being placed at 2 in 1,500,000.² For ethyl chlorid, I am able thus far, conjointly with my own 1,000 cases, to present you a record of 12,436 with but one bona fide proven death, forthwith to be narrated:³

A day laborer, 41 years of age, muscular, alcoholic, extensive ulcer of the leg. A transplantation operation was contemplated. Kelene narcosis for two minutes; extensive excitation; more kelene injected on the mask after three minutes. The blood being dark the mask was removed; cornea and pupil reflexes abolished; defensive motions with extremities; rigidity of the jaws; spasmodic breathing; cyanosis. Pulse was perceptible but not countable owing to the rigidity of the muscles; then followed an intermission of the pulse and death. The succession of events was instantaneous, the whole interval of time comprising three minutes. Five grains of ethyl chlorid were used. Artificial respiration was kept up one hour, camphorated oil injections were used, patient placed in the Trendelenburg position, cardiac massage, galvanism of the phrenics, all of no avail.

Postmortem.—Eccentric hypertrophy of the heart; fatty degeneration of the cardiac muscle; extensive arteriosclerosis of the coronary arteries; sclerosis of the aorta in moderate degree. Blood in the heart and veins of a cherry-red color, fluid, but not coagulated. The blood recalls poisoning by coal gas. No ecchymosis in the pericardium or pleura; no edema of the lungs. The absence of ecchymosis is noteworthy, hence no asphyxia can be charged. Extensive arteriosclerosis of the coronary arteries was assigned as the cause of death.

Lotheisen advises using but three grams at once and then to spray one gram of ethyl chlorid per minute until two grams are given. If marked excitation and cyanosis occur they demand the removal of the mask.

The details of another published death⁴ wrongly attributed to ethyl chlorid, I must needs bring to your notice. The consultant physician's statement is as follows:

A female, 55 years of age, kypho-scoliotic, came for the extraction of lower molars to her dentist. She was at times subject to cardiac derangement and within the year had suffered from a fracture of the rib and later from an attack of left hemiplegia. I had not seen her for one year until the message came that the patient was unconscious after a tooth extraction. I found the patient unconscious, automatic reflexes, absent corneal reflex, pupils contracted, jaw hanging, tongue not retracted, but limp; respiration intermittent, at intervals of two to three seconds two or three respirations, and at times deep sighs; expiration very slight; then another interval followed by the same type of respiration. Pulse 84, regular. The heart sounds clear; lungs free from disturbance; temperature 36.2 C. Color of the skin not blue, rather bright red cheeks. No odor emitted from the mouth; no vomiting; no incontinence. Flagellation and all else does not rouse her. Attempts at artificial respiration were of no avail; camphor and ether injections to the number of eight were ineffective.

The dentist's narrative reads thus:

The fear not unusual with a patient approaching the dentist's chair manifested itself in our patient. At 10 A. M., after drying the gums, moistening them with glycerin and guarding against the unnecessary inhalation of ethyl chlorid by covering the middle and index finger with a napkin and surrounding the lower teeth to be extracted, I sprayed the ethyl chlorid, at a distance of 35 cm., on the gums until they were blanched. Extraction required about twenty seconds, and two grams of ethyl chlorid were used. Following subsequent rinsing of the mouth, her head suddenly dropped, jaw sank, the face became pale and the eyes were dull and fixed. The pulse was weak. I exercised traction on the tongue, practiced artificial respiration, and provided for the access of fresh air. All this I kept up until 3 p. m. Until 10 o'clock at night

this collapsed condition continued, the pulse gradually weakened and accelerated up to 110; the respirations were 24. At 2:30 the next morning death set in. This was no asphyxia, but a suspension of consciousness and then a paralysis of respiration; finally terminating in cardiac paralysis. After the use of ethyl chlorid narcosis promptly set in, and so quickly were the cerebral functions in abeyance that the cortical centers and medulla became paralyzed. After fourteen hours death supervened.

This case of death attendant on the use of ethyl chlorid I can not let pass unchallenged. In the first place, ethyl chlorid was not used as advocated for narcosis. It was sprayed into the oral cavity in concentration. In the second place, the patient had one year ago experienced an apoplectic stroke, she was scoliotic and had compensatory changes traceable to cardiac insufficiency. Syncope set in immediately following the extraction. Similar phenomena are experienced in the first stages of chloroform and ether operations, particularly in operations conducted about the head and neck. Death under such circumstances has always been put down to reflex inhibitory action on the heart exerted through the vagi. In this fatal case of Seitz' death did not set in until fourteen hours later. Ethyl chlorid is too fugacious and too quickly eliminated to act thus long upon the system. From the vivid word picture of the patient's condition (note the description of Cheyne-Stokes' respiration) it is not far fetched to gain the impression of a possible apoplectic stroke perhaps due to embolism from the heart. Finally, the cause of death was not proven postmortem.

In Kocher's clinic there is mention, *en passant*, of a death under ethyl chlorid, but with no further detail whatsoever. It has subsequently been learned that in this instance the ethyl chlorid was not pure and not properly applied.

If these three deaths be unqualifiedly accepted, the mortality in the use of ethyl chlorid for narcosis approaches that of chloroform; if not, it stands between that of ether and gas. But we must be mindful that were all ether and chloroform deaths unstintedly reported we should have a higher mortality.

Symptoms bordering on fatality I have in my series encountered six times. In each instance they were those of respiratory interference and they occurred as the outcome of neglect of attention to the retro-placed tongue during the stage of profound narcosis, or a disregard of sufficient admixture of air. The fact that all of these patients recovered under artificial respiration speaks very favorably for ethyl chlorid. Thus Schleich⁵ found when he profoundly narcotized rabbits up to the point of respiratory paralysis with ether, chloroform and ethyl chlorid respectively, the animals succumbed to the former two, but were capable of resuscitation by artificial respiration when asphyxiated with ethyl chlorid. I have seen respiration in no wise adversely influenced, but if patients withhold from a free and easy respiration the ethyl chlorid will evaporate and not act as quickly. Such subjects as become deeply anesthetized breathe stertorously. Salivation I have never encountered.

Fritz König⁶ in animal experiments conducted on rabbits and monkeys, noted that in rabbits the respiration was accelerated and at times spasmodic. This was due to irritation of the respiratory center. In monkeys, however, this was wholly absent, and compared with ether given to apes, ethyl chlorid is far less dangerous.

These advantages claimed for ethyl chlorid obtain only when a due admixture of air is provided for. I have used ethyl chlorid with the labored respiration accompanying operations for empyema in three instances and I can pronounce it an ideal agent for this purpose. In retropharyngeal abscess with difficult respiration, it has also admirably stood the test in some twenty instances.

Some of the unpleasant experiences recounted were traceable to infants in whom we could subsequently make out the existence of the status lymphaticus (enlarged tonsils, enlarged adenoids and retropharyngeal lymph glands). We must not, however, jump at the conclusion that ethyl chlorid should not be used, therefore, in operations for adenoids, since the presence of the status lymphaticus once assumed would forbid the use of any anesthetic. Those who operate on adenoids quickly and who would take advantage of the expiratory efforts in the awakening to expel the blood, will see the advantage of this over nitrous oxid anesthesia with its invariably accompanying cyanosis and rigid jaw, and its superiority over a primary superficial narcosis with ether with its drawbacks of persistence of odor and prolonged nausea.

Even when given on an empty stomach, ethyl chlorid in a very small number of cases produces vomiting and nausea, but these are of the briefest duration when they do occur. Twitching and convulsive movements I have occasionally noticed during the anesthesia. Under these circumstances one must proceed cautiously in pushing the anesthesia. Of course these interfere with the finer manipulations of an elaborate operation; thus, decision of a cataract was performed with difficulty by a colleague owing to the rotary nystagmus of the eyeballs, though the anesthesia was perfect in every other respect.

A very few times the awakening has been accompanied by an excitement bordering on slight delirium, but of a very evanescent character. As a rule, it is phenomenal to witness time after time how naturally the patients come to and put questions. As for infants and children, the prompt and lusty cry after a previous profound narcosis is a source of great rejoicing to the parents, who welcome this sound with the same intense anxiety that they do the first cry of the new-born.

The pulse was always slightly accelerated with no alteration of its tension.

Very trustworthy and valuable experiments are again reported by Fritz König (loc. cit.) as to the influence of ethyl chlorid on blood pressure. He tested it on four rabbits and four monkeys, having provided for a free access of the proper amount of air by the employment of artificial respiration. His conclusions are as follows:

1. Ethyl chlorid administered with a due admixture of air effects no diminution of the arterial pressure, yet the narcosis is complete.

2. In individual instances there is a fall of blood pressure, due to vagus irritation. After section of the vagi the blood pressure rises and remains at its height throughout the narcosis.

3. When no due admixture of air is provided for, a lethal depression of the blood pressure and coincident respiratory paralysis follow. This holds good merely for the rabbit, the monkeys being far more resistant.

To effect a primary narcosis prior to the administration of ether or chloroform, ethyl chlorid is applicable in a like manner as laughing gas. It does not in the least act antagonistically or unfavorably towards accomplishing this.

As to the length of time during which it is applicable I see no reason why, if it operates well for fifteen minutes, it should not hold good for a greater length of time, in proof of which I can attest to its efficiency, having used it in an infant of 8 months for fifty minutes, the operation being for strangulated hernia; in a young lady of 18 for forty minutes in an operation for ganglia of the wrist, and in a woman of 75 for amputation of the metacarpal phalangeal articulation for tubercular arthritis, during a period of forty-five minutes. The item of expense strongly militates against its use in prolonged operations, as does also the readiness with which patients enliven and become rigid as soon as one desists in the administration because of the existing profound narcosis.

The present standpoint of ethyl chlorid narcosis may thus be summarized:

It is relatively a safe anesthetic.

Its danger point is not as readily nor as suddenly reached as in chloroform, nor does it carry with it the remoter dangers of ether.

Asphyxia when encountered is easily remedied by artificial respiration.

Proficiency in the giving of ethyl chlorid requires experience akin to that in the use of other anesthetics. The speedy onset of the anesthesia and the prompt recovery from it stamp it as ideal for ambulatory practice where it must in time usurp the preëminence of laughing gas. No physician of experience can say the least thing derogatory to the safety of laughing gas with its record of two deaths in 500,000 (?), but if you ask the physician wherefore he does not practice what is gospel in regard to laughing gas, the invariable reply is that even at its best the apparatus is too cumbersome and expensive and beyond control to estimate the quantity of gas at hand; furthermore, he will tell you the patients are always cyanotic and rigid. All these objections are at once overcome with ethyl chlorid. Surely, if every dentist is ready to use laughing gas to spare his patients pain in extraction with a minimum of unpleasant after-effects, why should not this be the attitude of the humane physician whenever he has recourse to the knife for the various acute and painful surgical affections.

In the mortality statistics given for nitrous oxid⁷ cognizance is taken of all the dental administrations. Were we also to include these, we should be able to say, not that the present mortality were 1 in 12,476 for ethyl chlorid, but 1 in 15,000 approximately. Again, the deaths from all causes to date under nitrous oxid are put down at 30 (loc. cit.); of these nearly one-half occurred within the last ten years, whereas that same number did not take place within three decades preceding. We offer this criticism not in any hostile spirit towards nitrous oxid, but merely to emphasize once more how cautious and reserved we must be in our attitude in estimating mortality statistics for a given anesthetic.

I submit these data, trusting that they will be sufficient to guide in giving ethyl chlorid a fair trial as a general anesthetic, so that it in due time may occupy a conspicuous place among the anesthetics.

⁷ *Anesthetics and Their Administration*, by Frederick W. Hewitt, p. 228, Second Edition.

To Preserve Rubber.—Ten to twelve parts of water and one part of ammonia will preserve soft rubber any length of time. Dip rubber pipes, etc., in a glass jar filled with this solution. Use for your ammonia bottle a rubber stopper; it is better than a glass stopper.—*Toledo Med. and Surg. Reporter*.

THE SUBARACHNOID INJECTION OF COCAIN. FOR OPERATIONS ON THE UPPER PART OF THE BODY.*

A. W. MORTON, A.B., M.D.

Professor of Surgery, College Physicians and Surgeons; Surgeon-in-Chief, Morton's Hospital; Visiting Surgeon, City and County Hospital; Consulting Surgeon, California General Hospital and German Hospital, and Surgeon to the Santa Fe R. R.

SAN FRANCISCO.

The use of cocain by the subarachnoid method was demonstrated by J. Leonard Corning of New York in 1884, later by Bier, Tuffier and others. During the past year it has been tried by most of the surgeons in the country for operations below the diaphragm, and by many of them discarded on account of objections of various kinds. It has been used in a few thousand cases, but not enough to establish its safety, as compared with the general anesthetics. Its analgesic properties can not be doubted for operations in the lower extremities.

I have found that the analgesia can be extended for operations in the upper part of the body. In the transactions of the State Medical Society of California, in April, 1901, I reported eight cases where I had extended the analgesia over the entire body.

I have now used this method 673 times without a failure of analgesia, and 60 of the cases were above the diaphragm. I have only found it necessary to give a general anesthetic once after the patient had been injected, and that was in a very nervous lady that I had injected with the pretention to make an examination and then administer an anesthetic before operating; I had curetted, and opened the abdomen to remove pus tubes before she realized I was operating, then she became alarmed, and it was necessary to give a little anesthetic to quiet her, still she admitted there was no pain. The patients have varied in age from eight to eighty-six years. Many of these operations have been on patients who have been in such condition from disease, or age, that it was not considered advisable to administer a general anesthetic. The operations have extended over all parts of the body. There has been only one fatality that could in any way be attributed to its use, and that I think could hardly be attributed to it from the condition of the patient, and the postmortem findings which will be found in the histories.

The advantage of this form of analgesia can readily be appreciated by any one who has observed the appearance of a patient during the time, and after he has passed through a serious operation under a general anesthetic; it not only takes time for the patient to regain consciousness, but there is a debilitated condition brought about by the effect of the anesthetic on the blood, the shock, and often the prolonged vomiting, as well as the operation, all of which tends to weaken the vitality of the patient, and invite the many complications, which too often follow a general anesthesia.

Under cocain analgesia with the most serious operations, we observe a patient conscious, bright, cheerful, hopeful, and every faculty in perfect control, able to converse, and take food and stimulants, and even to assist the surgeon if necessary. The after-disturbances, such as prolonged vomiting, suppression of urine, and bronchitis, seldom occur.

This form of analgesia can be used where a general anesthetic is contra-indicated, on account of diseased

heart, lungs or kidneys. It can be used for operations in the localities where it is extra hazardous to administer a general anesthetic, on account of blood entering the larynx, as in excision of the tongue, or where there is danger of involving a nerve in a ligature, as the recurrent laryngeal in removal of the thyroid gland. The great advantage to be gained in using this method in operations about the buccal cavity, can hardly be appreciated until tried.

Chemically pure cocain hydrochlorate is sterilized by exposing the crystals to dry heat 300 F. for fifteen minutes, then inclose in sterile tubes, or sealed envelopes, in proper doses until time of use. The dose varies from 0.3, 0.4 or 0.5 of a grain, depending on the locality, whether in the lower extremities, trunk, or head. This is the maximum dose for a strong person; young or old persons will take a smaller dose.

I use the Lures syringe, which has a glass piston, and graduated barrel, and is readily sterilized, and always in working order. The needle is made of steel wire tubing No. 19 gauge, and three inches long; the bevel is short, with the concave portion of it dulled, to prevent cutting plug of skin and obstructing needle. The needle is kept in a saturated solution of carbonate of sodium to prevent rusting.

The patient is placed in the reclining position on either side, with body curved forward, to separate the spinous processes; the spinous process of the fourth lumbar vertebra is located by being on an imaginary line connecting the crest of the ilium. The space just between the third or fourth lumbar vertebra is frozen with ethyl chlorid, after being thoroughly cleansed. The needle is introduced just beneath the spine in the median line, with the point of it directed upward, and introduced until it meets with diminished resistance, or fluid passes. Should the needle be obstructed, it can be opened by having the patient cough, using stylet, or making suction with syringe attached, at which time a drop of cerebrospinal fluid will pass. Then place the finger over the end of the needle and connect the syringe, which has 0.3 of a grain of cocain in it, with piston closed, and gradually withdraw the piston, until the syringe is half filled with cerebrospinal fluid, which readily dissolves the cocain; then gradually return the solution into the space, by pressing the piston.

Should the analgesia be desired in the upper extremities, introduce the needle in the third space, and use the same method as above, except the dose should be 0.4 to 0.5 of a grain of cocain, and introduce as rapidly as the piston of the syringe can be pressed, then withdraw the needle and seal with collodion.

The analgesia will be complete for operations in the lower extremities in from three to five minutes, and for operations in the upper part of the body, in from fifteen to twenty-five minutes; the analgesia lasts from one to three hours, and I have seen it last five hours.

I have seldom found it necessary to repeat the injections for prolonged operations, or incomplete analgesia, but should it be necessary, I see no objection to repeating the dose.

The action of such a small amount of cocain to produce profound analgesia has caused considerable discussion. I am of the opinion that it acts locally by coming directly in contact with the roots of the nerves, and it has a special affinity on the fibers which carry the sensation of pain.

The patient will occasionally complain of cramps in the limbs, or a warm sensation over the entire body, rapid pulse, perspiring, nausea, vomiting, involuntary

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard.

evacuation of the bowels during the early part of the analgesia, headache and chills after it. The vomiting occurs in about every eighth case, and usually comes on in about ten or fifteen minutes after the injection, and lasts only a few minutes; it is very seldom that it occurs after the operation. We often have a rapid pulse during the operation, especially if the patient is excited or nauseated. The rapid pulse is generally associated with the nausea, but there is sometimes a condition of depression which is evidently a form of shock due to some disturbance of the centers brought about by the injection, but I have never seen it very alarming, except in one case where I withdrew considerable cerebrospinal fluid for analysis.¹ The much dreaded headache will seldom if ever occur if the cocain is dissolved in the fluid, and none of the cerebrospinal fluid wasted. In dissolving the cocain in the cerebrospinal fluid, we not only disturb the parts less by placing a less amount of foreign element in the canal, but the fluid is kept at the same temperature, and is not in any way disturbed by diminishing or increasing the amount of fluid in the cerebrospinal space. If this is carried out you will seldom find headache. I have observed nine chills during the first few days after the operation; in some of them I was unable to find any cause for the disturbance, except it be this method of analgesia; there was no serious condition as a result.

Among the following operations many of the patients had two or more operations, only the most important one is mentioned.

Abdominal sections.....	63
Herniotomy for inguinal hernia.....	79
Herniotomy for umbilical hernia.....	2

CASE 1.—Mr. J. K., aged 39. Fracture of olecranon. Injected 0.4 cocain between the first and second lumbar vertebræ; analgesia complete in five minutes; pulse varied from 86 to 104; respiration 19 to 28; involuntary passage during the operation. Made an incision and wired the olecranon. During the operation the patient would grit his teeth, but expressed himself as free from pain.

CASE 2.—Mr. Wm. D. C., aged 55. Tumor of arm. Injected 0.4 gr. cocain into third lumbar space with force; analgesia complete to arms in five minutes; pulse varied from 90 to 100; resp. normal. Muscular tumor removed from arm.

CASE 3.—Mr. D. C., aged 67. Empyema of right side. Injected 0.4 gr. cocain into third space with force; analgesia complete to the axillary space in three minutes. Three ribs resected. Pulse varied from 98 to 114; resp. 20 to 24. Otherwise normal; some nausea.

CASE 4.—A. W. S., aged 49. Phlegmon of right hand. Injected 0.4 cocain into the second lumbar space, with much force; analgesia complete over the entire body in ten minutes; pulse varied from 80 to 94 after injection, 108 before injection from nervous excitement. Free incision in the palm and dorsal surface of hand; patient vomited.

CASE 5.—Mr. L., aged 60. Carcinoma sacrum and lower lip. Injected 0.4 gr. cocain into third lumbar space with force; analgesia complete over entire body in three minutes; pulse before injection 108, varied from 108 to 118, respiration normal. Carcinoma removed from sacrum and lower lip; operation lasted one hour and a half.

CASE 6.—Mr. J. B., aged 72. Chronic ulcer of leg and carcinoma on neck between shoulders. Injected 0.4 gr. cocain into third space with force; pulse varied from 75 to 94, resp. 13 to 20; no nausea or vomiting. Operation performed on back half an hour after injection.

CASE 7.—Mr. A. G., aged 41. Muscles torn from inner condyle of left arm. Injected 0.4 gr. cocain into third lumbar space; analgesia complete in five minutes; pulse varied from 80 to 114. Party was drunk and complained some during the operation, but seemed to be analgesic.

CASE 8.—Mr. F. O., aged 24. Tubercular glands of neck. Injected 0.4 gr. cocain into third lumbar space with force; pulse and respiration remained normal. Removed glands. Patient complained a little from pressure of retractors; pulse and respiration normal.

CASE 9.—Mr. R. K., aged 15. Mastoid abscess. Injected 0.4 gr. cocain into third lumbar space, then removed to ward, and was operated on by Dr. Payne. Mastoid opened free of pain; pulse and respiration normal. Two hours after operation boy was found walking in the ward with other patients, as though nothing had happened.

CASE 10.—Mr. A. L., aged 53. Abscess antrum, superior maxillary bone, left side, also general atheroma. Pulse before injection 92, respiration 20. Injected 0.4 gr. cocain into third lumbar space; after waiting twenty minutes, analgesia not complete about the face, then injected 0.1 gr. more; analgesia perfect as soon as injection was completed. Opened left antrum superior maxillary. Pulse varied from 80 to 110, respiration normal; slight vomiting ten minutes after injection.

CASE 11.—Mr. F. O. N., aged 43. Epithelioma of lower lip. Injected 0.5 gr. cocain into third space with force; analgesia complete in fifteen minutes; slight emesis thirty minutes after injection; pulse varied from 87 to 110; respiration normal. The entire lower lip removed, also glands of the neck, and lip was restored by plastic operation. Operation lasted two hours.

CASE 12.—Mr. J. G., aged 47. Fracture of seventh rib and perforation of lung. Injected 0.4 gr. cocain into third lumbar space, elevated and resected the ends of the ribs. Free from pain. Pulse varied from 100 to 110; respiration normal. Patient vomited after injection.

CASE 13.—Mr. H., aged 36. Gangrene of large toe and sebaceous cyst of scalp, size of hen's egg. Injected 0.5 gr. cocain into third space with force, analgesia complete, pulse and respiration normal. Toe was amputated three minutes after injection, and thirty minutes later cyst was removed.

CASE 14.—Mr. W. L., aged 42. Phlegmon of hand. Injected 0.5 gr. cocain into third lumbar space; analgesia complete in three minutes; pulse before injection 102, during operation it varied from 70 to 120, respiration 24 to 26.

CASE 15.—Mr. D. C. Empyema of left side. Injected 0.4 gr. cocain into third lumbar space; analgesia complete in three minutes. Resected a part of three ribs. Pulse before injection 98, and during operation 98 to 116; respiration 20 to 24. Patient was slightly nauseated.

CASE 16.—Mr. J. McD., aged 51. Carcinoma of both tonsils and soft palate. Injected 0.5 gr. cocain into third lumbar space with force; analgesia complete in ten minutes. Made free incision of each side of neck, and on the right side removed tonsil through the incision; the other tonsil and soft palate was removed, then cauterized the posterior space. Pulse varied from 80 to 100; respiration 20 to 24; analgesia was profound.

CASE 17.—Mr. M. J., aged 64. Carcinoma of lower eyelid and eye. Injected 0.5 gr. cocain into third lumbar space with force; analgesia over body in twenty-five minutes; patient complained a little at first incision, but did not flinch as the optic nerve was separated; slightly nauseated; pulse and respiration remained normal; operation performed by Dr. Dameron.

CASE 8.—Mr. K., aged 78. Carcinoma involving the upper eyelid; patient very feeble for years. Injected 0.5 gr. cocain into third space; analgesia complete in twenty minutes. Dr. Powell removed the upper lid and restored the parts by a plastic operation, and during the same time I removed a large lipoma from the left thigh. Patient talked and had no unpleasant symptoms; pulse dropped to 50, but soon returned to 65, which was normal.

CASE 19.—Mr. M., aged 54. Dislocation left shoulder. Injected 0.4 gr. cocain into third lumbar space; analgesia complete in fifteen minutes. Reduced dislocation; pulse and respiration remained normal.

CASE 20.—Mrs. H., aged 83. Carcinoma of left eye, patient very feeble. Injected 0.4 gr. cocain into third lumbar space; analgesia complete in twenty-five minutes; pulse varied from 70 to 100; respiration, 20 to 24; patient vomited before operation commenced. Dr. Payne enucleated the eye and performed a plastic operation on lower lid.

CASE 21.—Mr. E., aged 36. Mastoiditis. Injected 0.4 gr. cocain into third lumbar space; analgesia complete in thirty minutes; patient nauseated; pulse varied from 72 to 104; respiration 20 to 22. Mastoid opened and curetted.

CASE 22.—Mr. Mc, aged 30. Sarcoma of tongue. Injected 0.5 gr. cocain into third space; analgesia complete in twenty-five minutes; patient struggled a little at first, as blood passed into the back part of the mouth, but after the blood was removed patient kept quiet. The tongue was removed through the mouth, and there was considerable hemorrhage. Pulse before operation 100, during the operation pulse was 130, but remained about 110; respiration from 20 to 26. Later the growth returned on the base of the tongue and tonsil. Injected 0.5 gr. cocain; analgesia complete in twenty-five minutes. The glands were removed from each side of the neck, parotid, submaxillary, both tonsils and base of the tongue. The pulse before operation was 104, during operation pulse varied from 112 to 140; respiration 22 to 26. The operation lasted two hours, during which time the man showed no signs of pain. At close of operation the man thanked the operator, Dr. Kenyon, by nodding; the patient was up in a few days, but the growth soon returned.

CASE 23.—Mrs. E. Carcinoma of breast, and very feeble with mitral regurgitation. Injected 0.4 gr. cocain into third lumbar space; analgesia complete in ten minutes; patient vomited; pulse rate varied from 90 to 115, and very feeble during operation. Used hypodermic stimulations. The breast was removed without pain.

CASE 24.—Mr. P. C. R., aged 45. Infraorbital neuralgia, of a severe type. Injected 0.4 gr. cocain into third lumbar space, the entire body analgesic in twenty minutes; pulse and respiration remained normal. The patient found only temporary relief.

CASE 25.—Mr. A. M., aged 43. Osteoma in the orbital cavity, which caused the eyeball to bulge. Injected 0.5 gr. cocain into third lumbar space; analgesia complete in twenty minutes. Free incision made above the eye through the upper lid; the eyeball was pushed downward and forward and growth removed. Everything remained normal, and the patient constantly expressed himself as feeling all right. Operation by Dr. Schloss.

CASE 26.—Miss C. C., aged 16. Deflected septum and exostosis. Injected 0.4 gr. cocain into third lumbar space; analgesia complete in twenty minutes; patient vomited, pulse rate varied from 80 to 100, respiration 20 to 22. Patient complained a little of pain during the operation. Operation by Dr. Schloss.

CASE 27.—Mr. B., aged 48. Injury to hand, fingers of hand in complete extension. Injected 0.5 gr. cocain into third lumbar space; analgesia complete in fifteen minutes; pulse varied from 72 to 102; respiration normal. The extensor tendons were cut and ankylosis broken down. Patient vomited before operation.

CASE 28.—Mr. H. A., aged 58. Injury to left arm. Injected 0.4 cocain into third lumbar space; analgesia complete in seven minutes. Muscles stitched and parts grafted. Pulse and respiration remained normal.

CASE 29.—Mr. W. H., aged 48. Carcinoma of lower lip. Injected 0.5 gr. of cocain into third lumbar space; analgesia complete in twenty minutes. Removed the lower lip and restored the parts by a plastic operation. Pulse before injection 104, varied during operation from 104 to 119; respiration 20 to 24.

CASE 30.—Mr. A. L., aged 52 years. Carcinoma superior maxillary bone of left side. Injected 0.4 of cocain in third lumbar space, and at the end of twenty minutes did not show profound analgesia. Injected 0.2 gr. more into third lumbar space; analgesia immediately after second injection. Removed the left superior maxillary bone and alveolar border of right side. Pulse varied from 70 to 100; respiration 20 to 24; patient nauseated; gave hypodermic strychnin during operation. Recovery was uninterrupted. Patient died eight months later.

CASE 31.—Mr. F. C., aged 42. Epithelioma of lip. Injected 0.4 gr. cocain into third lumbar space, with force; analgesia complete in twenty-five minutes; pulse varied from 76 to 104; respiration 20 to 23; vomited. Removed the glands from the neck and the whole side of the lower lip, which was restored by plastic operation.

CASE 32.—Mr. J. W. H., aged 26. Carcinoma of left breast. Injected 0.5 gr. cocain into third lumbar space; analgesia complete in twenty-five minutes; pulse varied from 78 to 98; respiration 20 to 25. Removed the breast and axillary glands.

CASE 33.—Mr. A., aged 51. Empyema of antrum left side. Injected 0.4 gr. cocain into third lumbar space, with force; analgesia complete in twenty minutes. Opened and drained antrum of superior maxillary. Pulse and respiration remained about normal.

CASE 34.—Mr. J. B., aged 52. Carcinoma of tongue, tonsils and glands of the neck; the base of the mouth had broken through, and the tongue was so much enlarged that the patient could not swallow. Injected 0.5 gr. cocain into third lumbar space, with force; analgesia complete in twenty-five minutes; pulse varied from 112 to 120; respiration 22 to 26. Removed the tongue through the base of the mouth, and opened the neck and drained. After the operation patient was fed with stomach tube. Died ten days after the operation, from his emaciated condition.

CASE 35.—Mr. F. H., aged 31. Ununited fracture of right humerus. Injected 0.5 gr. cocain into third lumbar space; analgesia complete in twenty minutes; pulse varied from 80 to 124; respiration 20 to 27. Wired the bones.

CASE 36.—Mr. J. D., aged 53. Carcinoma of tonsils and inferior maxillary of right side. Injected 0.5 gr. cocain into third lumbar space; patient vomited before operation; analgesia complete in fifteen minutes. Removed one-third of the inferior maxillary bone, both tonsils, glands of the neck, and cauterized the posterior nasal space with a Paquelin cautery. Pulse varied from 100 to 128, being the highest while working in the deep structures of the neck. Respiration 18 to 28.

CASE 37.—Mr. J. B. M., aged 63. Carcinoma of right inferior maxillary and tonsil. Injected 0.5 gr. cocain into third lumbar space; analgesia complete in twenty minutes. Removed part of the inferior maxillary bone, both tonsils, and glands of the neck. Patient walked to carriage, and rode home some two hours after operation.

CASE 38.—Miss S., aged 27. Exophthalmic goiter, size of hen's egg, with very rapid pulse, and a general weakened condition of the system. Pulse before operation varied from 120 to 130, respiration 22 to 26. Injected 0.5 gr. cocain into third lumbar space, with force; analgesia complete in twenty-five minutes. Removed right gland through a curved incision. During operation I made certain not to include the recurrent laryngeal nerve in my ligature, by noticing the condition of the voice. The patient complained a little from tension, so that it was necessary to administer a little alcohol on the mask, which quieted her, as she thought we were administering chloroform. The operation lasted one hour, and patient made a rapid recovery.

CASE 39.—Mr. J. D., aged 52. Carcinoma of neck. Injected 0.4 gr. cocain into third lumbar space; analgesia complete in twenty minutes. Removed glands of the neck. Pulse varied from 72 to 100; patient vomited.

CASE 40.—Mr. M., aged 52. Trephining frontal antrum. Injected 0.4 gr. cocain into third lumbar space; analgesia complete in twenty-five minutes. Frontal antrum trephined. Patient complained very little; no vomiting or nausea.

CASE 41.—Mr. C., aged 63. Carcinoma of the tongue. Injected 0.4 gr. cocain into third lumbar space; analgesia complete in seven minutes. Removed the tongue and glands of the neck. The operation lasted two hours, no vomiting or any bad after-effects. Pulse varied from 72 to 104. In twenty-five minutes after operation started patient complained a little, but very little after first incision.

CASE 42.—Mr. W., aged 33 years. Subclavian aneurism, with paralysis of left arm. Injected 0.4 gr. cocain into third lumbar space; analgesia complete in twenty minutes. Amputated arm at shoulder joint. Patient made a rapid recovery.

CASE 43.—Mr. T. B., aged 72. Carcinoma on back. Injected 0.3 gr. cocain into third lumbar space; analgesia complete in twenty-five minutes. Carcinoma removed.

CASE 44.—Mr. A., aged 42. Trephined antrum of superior maxillary. Injected 0.4 gr. cocain into third lumbar space; analgesia complete in twenty minutes; pulse varied from 70 to 80; little nausea. Trephined antrum.

CASE 45.—Mr. W., aged 52. Trephining depressed fracture. Injected 0.4 gr. cocain into third lumbar space; analgesia complete in fifteen minutes. Opened scalp over right side, and elevated a depressed fracture, size of silver dollar. Patient was nauseated.

CASE 46.—Spanish boot-black, aged 24. Fibroma of superior maxillary. Injected 0.5 gr. cocain into third lumbar space; analgesia complete in twenty-five minutes. Patient was frightened and complained a little as incision was made in skin, otherwise little evidence of pain.

CASE 47.—Mr. —, aged 7. Contracted sterno-mastoid; was severed twenty minutes after injecting 0.3 gr. cocain into third lumbar space.

CASE 48.—Mrs. B., Swedish, aged 54 years. Height 5 feet 1 inch, general weight 348 pounds. Had recently reduced weight by dieting to 318 pounds. Alcoholic subject, with a rheumatic history, and a pendulous abdomen, which was hanging over half way to the knees, in which was a constricted umbilical hernia. The heart sounds were very weak, with a mitral murmur, and pulse rate 120. There were symptoms of strangulation, and I was unable to reduce the hernia. The patient had been unable to take the reclining position for sev-

eral days on account of her heart affection, and was in nearly a semi-comatose condition at the time of injection, from the strangulation. After consultation it was decided unwise to administer an anesthetic. Injected 15 m. of 2 per cent. solution of cocain into fourth lumbar space, made two oval incisions connecting on each side of the abdomen and removed 14 pounds of the pendulous abdomen, and then liberated and reduced the hernia, at which time she expired. The post-mortem was made in less than one hour after death. Pericardium was completely distended, 200 c.c. clear fluid; the heart cavities greatly distended by fluid blood; the heart was very much enlarged, and light in color; posterior segment of the tricuspid adherent to the wall of the ventricle, chordæ tendinæ contracted, forming fibrous tissue, which extended into the ventricles, showing evidence of old ulceration; mitral segment adherent to ventricle, through chordæ tendinæ, and filled with calcareous deposits in the margins. Atheroma of aorta. 615 Parrott Building.

DISCUSSION

ON PAPERS OF DRS. WARE AND MORTON.

DR. DANIEL N. EISENDRATH, Chicago—When ethyl bromid and ethyl chlorid were first brought out they were given in too concentrated a form and were then dropped. The apparatus of Dr. Ware seems to solve the question and makes the anesthetic less dangerous. It is a good anesthetic for dispensary practice and German surgeons have used it a great deal for small operations. They have been very successful, the mortality being very small. This form of general anesthesia is better than the nitrous oxid, which has to be given very carefully to elderly patients, as the sudden increase of arterial pressure is likely to lead to serious results.

There is an element of medullary anesthesia which we are apt to forget and that is mental shock. I operated on a patient 80 years old, a week ago, but on account of his atheromatous heart I hesitated to give either ether or chloroform, and performed a laparotomy under local anesthesia. The cut through the skin gave very little pain. There was some rigidity of the abdominal muscles. From the moment I got into the abdominal cavity the element of mental shock played a great rôle. He could scarcely ever feel that I was touching the stomach, but the consciousness of a major operation being performed seemed to distress him very much. I am inclined to believe that this does more harm than even the general anesthetic would.

DR. C. E. THOMSON, Scranton—I think this is an appropriate time to report that in the institution with which I am connected we have lost two cases from chloroform anesthesia this year. Both cases were fractures of the lower jaw. In the first case the anesthetic was being given for a simple operation. Not more than a dram of chloroform had been used, when the patients suddenly stopped breathing and died. Since I left home this week, in a letter received last evening, my associate reports a second death from chloroform used in reducing a double fracture of the lower jaw. In this case he gave the anesthetic himself and the patient took but a few drops when he stopped breathing. The doctor did a tracheotomy and the patient gasped a few times and then died. I want to report these cases, which are to me interesting, as proving in this connection that local anesthetics are safer. We have used chloroform for fifteen years without a death, except the above.

DR. D. F. MONASH, Chicago—It is evident that ethyl chlorid as a general anesthetic must have a limited range of application, as it is employed only in minor operations of brief duration. Next to nitrous oxid gas it appears to be the safest and most rapid anesthetic we possess, and enjoys the advantage of a full return to consciousness immediately on the removal of the drug and produces no disagreeable after-effects. In the large experience of the essayist, chlorid of ethyl has proven a safe and practical anesthetic. The rapid induction of anesthesia, the speedy return to consciousness without apparent effect on pulse or respiration, without cyanosis, vertigo or nausea, and the simplicity of administration should popularize its use. For these reasons ethyl chlorid may have a field of special usefulness as a dispensary and office anesthetic. The discovery of the general anesthetic effect of ethyl chlorid, it is said, was

made by a dentist who, in spraying it on a patient's gums, noticed the constitutional effect produced by its inhalation.

DR. W. D. HAINES, Cincinnati—I have long held that death from chloroform is occasionally due to the irritating influence of the fluid on the faucial mucous membrane of the patient. The administration of chloroform is frequently intrusted to a student who has had little or no experience in giving the drug and who, through lack of attention or knowledge, drops the chloroform on the mask too rapidly and the liquid begins to run over the patient's face; if the mouth be open some of the fluid may readily find its way to the throat of the patient, who ceases to breathe at once and defies all attempts at resuscitation. I drew this conclusion from my experience in sudden deaths from carbolic acid. Many of these cases die instantly just as do the chloroform cases, long before the physiologic effect of either drug could become operative. Therefore, I submit that death in such instances is not due to chloroform narcosis on the one hand or carbolic acid poisoning on the other, but is due to inhibition. The tendency of any irritant to the faucial mucous membrane is toward inhibition, from its influence on the filaments of the vagus which are so freely distributed to these parts. Hence it is well for the surgeon, when operating on these parts, applying caustics to them or in the administration of chloroform to remember the neck as one of the "privileged regions."

DR. R. C. CORFEX, Portland Ore.—I believe much more importance should be attached to the anesthetist than to the anesthetic. We have stopped having students anesthetize for us, and instead we have a salaried man, whom we consider a man of equal judgment and mental ability with the operator. The trouble in anesthesia is in the man who is giving it. Since we have commenced the employing of an experienced anesthetist, we have entirely forgotten the phrase, "This patient takes the anesthetic very badly." When we were employing inexperienced doctors or medical students, we were frequently stopped in the operation to use artificial respiration or to in some other way help the anesthetist. The point of importance in the giving of an anesthetic is for the anesthetist to know exactly "where his patient is." There are many minor points in the facial expression, in the circulation, in the eyes, which are of vital importance and tell the experienced anesthetist when his patient is getting on dangerous ground. An inexperienced anesthetist (and I mean in this class the man who never learns the meaning of small symptoms, even though he has had years of experience) can not tell the difference between the rapid heart, due to excitement, in the spasmodic stage, and the heart which is flagging from paralysis. Frequently we find this kind of an anesthetist using artificial respiration while the patient is still talking. In the small towns and country districts it is a very frequent thing for us to hear of several men in the neighborhood who have such strong constitutions that Dr. — could not get them under the anesthetic at all. I think if there is a burning shame resting on surgeons to-day it is that they allow inexperienced physicians and medical students to do anesthesia, when it is in reality but little less important than the operation itself. If patients only knew the great danger they are in when they believe "that anyone can give the anesthetic," they would certainly be willing to pay any price for a man who has learned by study and experience the symptoms which indicate the position the patient occupies at all the stages of the operation as regards the anesthetic. As to the choice of general anesthetics, I think there is very little. The man who is accustomed to give chloroform will give chloroform with as much safety as the one who is accustomed to giving ether will give that anesthetic. Our anesthetist uses ether and by his method gets the patient under the anesthetic in from three to five minutes. During the past seven months, he has given for us more than four hundred anesthetics, and so far as I know the operator has not once been asked or found it necessary to stop his operating to look after the condition of his patient because of the anesthetic.

DR. WARE, in closing—I think I have embodied all I have to say in my paper. It being a new subject, I hardly looked for extensive discussion. Like everything new it has to be tried first. I thought after I had given this anesthetic in 1,000 cases I was entitled to give my experience. I had always been

a great admirer of laughing gas, having given it as many as 5,000 times or more without fatality. While demonstrating to a colleague who was anxious to see the method of its use, we gave a patient laughing gas and to my great surprise he narrowly escaped death. Anyone will meet with a death occasionally with every anesthetic, and herein we must consider the personal equation of the anesthetizer. If you want an anesthetic that will be free from any mortality I think you are certainly looking for an unknown quantity. With these phenomena of threatening death that occur so suddenly I have had the experience repeatedly that carefully executed artificial respiration instead of tracheotomy is the proper procedure. Dr. Crile has shown what a rôle the pneumogastric and its branches play in operative work about the neck. To eliminate these baneful influences wrongly attributed to chloroform, he blocks out reflexes by application of cocaine to the pneumogastric and its branches as exposed.

DR. MORTON, in closing—The one great objection to this form of analgesia is that the patient remains perfectly conscious during the operation, which might interfere with a nervous person; this is perfectly true as we have been educated to believe that it is necessary to be unconscious during the performance of a capital operation. In some of those cases it will require a little tact and suggestion on the part of the surgeon to distract the patient's mind from the operation, and it may be necessary before performing the operation to blindfold the patient, and should you not wish him to understand what you are saying close his ears with cotton. By using this method of injecting the cocaine directly into the cerebrospinal fluid, you will never have a failure of analgesia, as it is necessary to get the needle into proper space before you can dissolve the cocaine. The crystals of cocaine are readily sterilized by exposing to dry heat at a temperature of 300 F. for fifteen minutes, and they will keep indefinitely, and are always ready for use. The solution of cocaine is very difficult to sterilize without boiling, and the analgesic properties will not stand boiling. It will soon become old and form products which are poisonous. This method of analgesia places less foreign matter in the subarachnoid space, which naturally makes less disturbance.

SYPHILIS OF THE LIVER.*

CHARLES G. STOCKTON, M.D.

BUFFALO.

Two notable contributions on the morbid anatomy of hepatic syphilis, the one by Adami¹ the other by Flexner,² render superfluous any review which I might make of this part of the question. Although the chief pathologic changes induced by syphilis of the liver appear to have been carefully studied and classified, the clinician occasionally meets with instances of undoubted syphilis in which there develop hepatic manifestations that so puzzle him as to the precise character of the morbid change that classification has to be abandoned. There is abundant literature of the classical expressions of the disease with which all recognized students substantially agree, and there are to be found many scattered reports of individual cases that are sufficiently rare to warrant description; but these are so commonly benefited by treatment that they either escape autopsy altogether or else are delayed until the specific effects of mercury or iodid have helped to conceal the exact steps of the morbid process. It is apparent that there is no fundamental difference between the pathology of congenital syphilis and that of the acquired disease. In either one we may have first: the diffuse hepatitis or parenchymatous degeneration to be succeeded by the ingrowth of fibroid tissue; these changes are probably due to the local

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. Frank A. Jones, George Dock and J. M. Anders.

2. New York Med. Jour., Jan. 18, 1902.

effect of the specific toxin rather than to local infection. Second, we have gummata occurring in large tumors, in scattered masses, in miliary granulomata, or in the budding stage, as mere aggregations of lymphoid cells; these lesions appear to be the outcome of stimulation of tissue from the local action of micro-organisms rather than intoxication. In some instances the liver is apparently invaded chiefly through the lymphatic system, not infrequently by the route of the peritoneal cavity, in which case the liver is often attacked at the periphery; and still other cases in which the disease manifests itself especially in the blood vessels, producing the most striking symptoms by obstructing some branches of the hepatic veins, as pointed out by Fagge; or by the obliteration of some of the portal branches or distribution of the hepatic artery.

Among the clinical manifestations excited by the changed structure of the organ (not overlooking the constitutional effects of the accompanying toxemia) are, first, increased bulk of the liver; second, deformity of its contour; third, roughening of the adhesions to its surfaces; fourth, obstruction of the bile passages, causing jaundice; fifth, obstruction of the blood passages, causing ascites; sixth, perihepatitis, causing friction, pain, tenderness and sometimes contraction of the liver; seventh, and rarely, an extraordinary enlargement of the liver, sometimes accompanied by perihepatitis, slight effusion, pain and tenderness, apparently the result of lymphatic obstruction. Disturbances in nutrition leading to emaciation and glycosuria is not uncommon, and almost invariably there is some albuminuria with presence of tube casts. In addition to these is the cachexia of syphilis, which belong no more to syphilis of the liver than to that of the other organs of the body.

The most mysterious changes of the liver that have come under my personal observation have been in a few rare cases of syphilitic disease expending its force for the most part on the lymphatic system. I do not refer to the ordinary cases of perihepatitis, with pain, friction, moderate increase in hepatic bulk, perhaps to be followed by contraction, and not infrequently extending along the capsule of Glisson and invading deeper structure of the organ. Such cases are sufficiently familiar. I refer rather to a class of cases, one of which I saw years ago when a hospital interne, in which there had been evidence of serious involvement of the deep abdominal lymphatics. There was a low-grade peritonitis, and probably the disease was at the same time active in the retro-peritoneal lymph nodes. Throughout the abdomen, widely diffused, could be distinctly felt resisting masses tender to the touch. There were also apparently periphepatitis and a slight accumulation of ascitic fluid. The liver already enlarged, extending slightly below the free border of the ribs, somewhat suddenly began increasing in bulk and, within a fortnight, had reached a point midway between the umbilicus and the pubis. Its border was smooth, rounded, without any irregularities, and was tender on pressure. This was the largest liver which has come under my observation. Under treatment by potassium iodid in large doses and inunctions with mercurial ointment, improvement rapidly occurred and within a month the liver had returned almost to its normal size and the patient was restored to a reasonable state of health. There was no jaundice, but, as stated, moderate ascites; this, however, probably depended on the accompanying peritoneal lymphatic involvement rather than on the liver. The digestion was disturbed, the patient suffered from pain and there was considerable elevation of temperature. I have never been able satisfac-

torily to account for this process—the sudden and very great enlargement of the liver and its subsequent restoration by specific treatment within an incredibly short time is something that has never been sufficiently explained, so far as I know, by the pathologist.

I have since had the opportunity of studying an almost identical case. This condition does not seem like the pericellular cirrhosis with parenchymatous degeneration, resulting from the intoxication (either of infections or poisons) such as has been described by Aufrecht, for the reason that under treatment the liver rather promptly returns to a state of reasonable competency. Taking into consideration the fact that the lymphatic system was in both these cases markedly involved, and recalling that the lymph glands when thus affected show infiltration with round cells, it has seemed to me probable that a similar process was taking place in the intercellular and interlobular lymph spaces of the liver. Be the cause what it may, the hepatic enlargement seems to be unquestionably purely specific. Besides the increase in bulk there was pain and tenderness, at times very severe, not only in the region of the liver, but in other parts of the abdomen. In congenital syphilis it is known that the liver occasionally reaches a great size, a change that has been shown to depend on pericellular cirrhosis associated with parenchymatous degeneration, but in these instances death usually results within a few weeks. Because of the presence of pain and tenderness the question of perihepatitis naturally arises. It is highly probable that there was perihepatitis present, although a friction was at no time heard; but the case was quite unlike the ordinary instances of syphilitic perihepatitis with only moderate increase in the size of the liver, with friction sound and pain appearing on slight movement. Nor is it like those cases involving the capsule of Glisson, usually associated with the formation of gummata in which dense bands of fibrous structure extend through the organ and, on contraction, leave it deformed by prominent ridges and deep depressions. Such a case came recently under my observation. The man was 36 years old and had acquired syphilis eighteen years before. He had lost thirty-two pounds in weight within a few months; his skin was subicteric, pigmented and harsh; his blood vessels were sclerotic with the resulting changes in the heart and kidneys. There was neither ascites nor distinct jaundice. Chains of slightly enlarged lymph glands could be found. The liver was two inches below the free border of the ribs and deep lines with intervening prominences in the liver could be most readily felt on palpation. This patient is at present improving on mercurial inunctions. It is altogether probable that we have here to deal with a case in which gummata have formed and radiating from these through the liver and appearing on its surface and involving its capsule are dense bands of fibrous tissue.

We usually find moderate enlargement of the liver in diffuse syphilitic hepatitis. It is a condition generally accompanied by a wide symptomatology and sometimes baffles treatment. Nevertheless, when the parenchyma has not undergone too much degeneration, radical measures will often accomplish wonders. I report the following case in illustration of the foregoing statements, and especially because of the question of diagnosis.

CASE 1.—C. E. B., aged 45, American, single, bar tender, entered Buffalo General Hospital, Jan. 30, 1901, complaining of sore throat, pain, swelling of right wrist, cough, expectoration, dyspnea on exertion, and digestive disturbance.

Family History—Father died at 74, mother at 84; two brothers and two sisters alive and well; one brother was killed in Civil War, and one died from tuberculosis.

Personal History—Patient had suffered from several diseases of childhood, including scarlet fever, and had had several attacks of rheumatism, the first of which occurred five years ago. He had influenza twice. At sixteen years of age he acquired syphilis for which he was treated for a period of two years. He stated that the present trouble began a week before entrance. He had apparently taken cold and suffered from a pharyngitis and tracheo-bronchitis. The patient weighed 250 pounds and was about five feet ten inches high. His tissues were flabby, muscles poorly developed. The right wrist was somewhat swollen and painful. The skin was muddy, icteric, and there was acne rosacea on the face. The temperature was normal, pulse 90, rather quick, small, but of good tension. The heart was slightly enlarged, the first sound at the apex weak, although the aortic second was over accentuated. The abdomen was very fat and was further distended by ascitic fluid, and the large liver, which extended two inches below the free border of the ribs. January 31, the urine was very dark, 1030 specific gravity, highly acid, containing bile-pigment, a trace of albumin, but no sugar. There were a few bile-stained hyalin casts, renal epithelial cells and leucocytes. February 1, he was found to pass 500 c.c. of urine in 24 hours, containing 34.9 grams of solids, 17.5 grams of urea, considerable indican, and some bile-stained, coarsely-granular casts.

Treatment—The volume of the liver steadily increased and also the ascites, although the man was given purgatives, diuretics, vapor baths and circulatory stimulants. He was given one gram of potassium iodid three times a day with 30 gm. of pil. hydrarg. at night, followed by sodium sulphate in the morning. Ung. hydrarg. was applied to the painful joints. He improved in his symptoms with the exception of the ascites and the liver, which apparently grew worse. The fluid steadily increased, and toward the end of February, the liver extended from the nipple to the umbilicus, a distance of about ten inches. The general condition of the patient was better. March 5, the abdomen was tapped, and 3000 c.c. of bile-stained fluid withdrawn. The iodid was increased and inunctions of mercury applied systematically. With the application of the latter the man began to improve. The ascitic fluid did not reaccumulate and the liver decreased in size.

Results—The patient was discharged April 17 feeling very well. The lower border of the liver was at the free border of the ribs; it extended upwards to the nipple; it was still large, but the jaundice had disappeared and the man had largely regained his strength. At this date, fourteen months after his discharge, the patient has continued improving. The treatment has been continued at intervals.

By a singular coincidence I had in my wards at the same time another case almost the identical counterpart of this in every way. The ascites was so great that he was frequently tapped, but he was ultimately so far restored that he left the hospital hoping to be able to earn his living.

It is not uncommon to find evidence of a single large gumma, often so superficial that it can be made out by palpation, and frequently accompanied by localized perihepatitis. These cases are often mistaken for malignancy, and as the diagnosis is somewhat difficult it may be worth while to report the following illustrative case:

CASE 2—William K., American, aged 28, hotel clerk. Entered Buffalo General Hospital, Sept. 13, 1900. Complained of fever, weakness and pain in the right hypochondrium.

Family History—Mother died at 52 of inflammation of the bowels; father at 65 from an unknown cause. Two sisters and one brother were alive and well. The patient had had but one child born, apparently healthy, but when seven days old began to have hemorrhages from the penis, which recurred frequently for five days until the child died.

Personal History—The patient acknowledged having had a urethral discharge about ten years ago from which he says

he recovered after two weeks' treatment. He denied syphilis positively; no scar could be found; he had used alcohol moderately. The history was otherwise unimportant. The present illness began about two years ago, when the patient complained of pain under the free border of the right ribs which continued for about two months. He then improved, and believed himself to be in good condition until May, 1900, when the pain returned in the same region, extending into the lower thoracic region of the right side. All treatment failed and he steadily grew worse. He formerly weighed 158, but on entrance to the hospital weighed 120 pounds only. He complained of night sweats, loss of appetite, gastric distress after eating, insomnia and great weakness. He had no chills although there was a rise of temperature. Bowels were usually constipated, but were relieved by purgatives. A study of the temperature showed that without any regularity it ranged from 96.5 to 101 degrees F., and the pulse varied from 70 to 100, corresponding in its variation with the temperature. When awake the respirations were uniformly at 20.

Examination—The physical examination showed that the thorax was negative. There was no abdominal distension, save slight fulness in the right hypochondrium. The area of hepatic dulness was of most interest, extending from the fifth rib to a point slightly above the transverse umbilical line. Palpation confirmed the belief that this was owing to enlargement of the liver, which increase was limited to the right lobe. The lower border of this could be made out as a rounded and comparatively smooth mass, not tender to pressure, apparently non-adherent and its movements accompanied by friction sound. There was no evidence of disease of the gall-bladder. A careful search revealed a few slightly enlarged lymphatic glands in various regions of the body. In other respects the man presented no evidence of syphilis. The blood examination showed 4,883,000 erythrocytes, 9650 leucocytes—a ratio of 1 to 506; hemoglobin was 75 per cent. Analysis of the stomach contents, after an Ewald test breakfast, showed 60 c.c. of expressed pure contents. Free hydrochloric acid .156, total combined hydrochloric acid .078, total organic acids and acid salts .039, total acidity 27.3. There were found present erythrodextrin, pepton and free albumin. Microscopically, it was negative. The urine examinations were negative.

Diagnosis—In the diagnosis the question of malignant growth, tuberculosis and gumma of the liver were considered. September 14 five milligrams of tuberculin were injected and his temperature thereafter taken every two hours for forty-eight hours. It showed a sharp rise to 101.4, but thereafter remained subnormal until the 16th, when he was given an injection of eight milligrams of tuberculin, after which his temperature rose sharply to 100.5, and again fell to subnormal, and remained so until the 20th, when he was given ten milligrams without a reaction. It was concluded that the condition was not tubercular. The evident, though slight, reaction to tuberculin increased the suspicion that the condition was syphilis, as a moderate reaction to tuberculin has occasionally been observed in the late manifestations of that disease. The history in the case pointing to trouble two years past, the general characteristics of the enlargement of the liver, the absence of irregularity, and evidence of primary carcinomatous focus, led us to exclude malignancy.

Treatment—The diagnosis of gumma of the liver being made, the patient was given potassium iodid in doses of twenty grains before meals, which was discontinued on the 24th, and was replaced by daily inunctions of mercurial ointment.

Results—Three days later the patient was unquestionably better. The treatment was continued. On the following day his weight was found to be 128 pounds. From this time on his progress continued, his color returned, appetite improved, his weight increased, and the tumor steadily decreased in size. In the early part of October the liver was apparently of normal proportion. The man was discharged from the hospital with directions to continue treatment.

It is possible for a gumma of considerable size to develop in the liver without the association of marked constitutional symptoms, as the following case illustrates:

CASE 3.—A man, aged 39, a merchant of good habits, was referred to me because of the appearance of a lump in the right side which was believed to be malignant. The man appeared to be in fair health, although he said that he had lost 25 pounds, suffered slightly from dizziness and weakness and pain under the right ribs, which was made worse when lying on the left side. His temperature was elevated one degree, his pulse rather weak, his digestion good. The mucous membrane of the mouth was unhealthy and the skin somewhat sodden in appearance. He passed 1000 c.c. of urine in 24 hours, specific gravity 1016, containing 20 grams of urea, an excess of indican, no albumin; a few cylindroids. The examination of the stomach contents showed a good gastric condition. The specific gravity of the blood was 1056, erythrocytes 4,760,000, leucocytes 10,400, hemoglobin 75 per cent. The differential count showed 78 per cent. of polynuclear cells. The red cells were somewhat pale with some megalocytes, microcytes and poikilocytes present. The man had not the cachexia of malignancy. I found on the upper lip, about one-half inch above the mucosa, a characteristic scar, and learned that when a boy about sixteen years old he had some kind of a wart-like sore, which was succeeded by an eruption on his body, for which he took medicine, and made a good recovery. He could not account for the presence of the sore and denied any venereal history. He was treated by a course of mercurial inunctions and made immediate improvement. Three months afterwards the tumor had disappeared. This man has been under observation for two years, and during the last year has been in perfect health.

This case is especially interesting in showing how easily one may be misled by the nature of a tumor. The man was emphatic in his denial of syphilitic infection, and was surprised when I explained to him my belief as to the nature of the disease. Beside that, his general health was less disturbed than might have been expected with a tumor the size of a baseball growing in the lower portion of his liver. It is generally conceded that serious syphilitic lesions of the liver occur only in the last stages of the disease. With the exception of perihepatitis and lymphatic involvement, I am convinced that this is true. The last-named lesion I have seen at a comparatively early period. Besides this, I am satisfied that in the early stages of the affection we find the liver congested, moderately enlarged, somewhat tender and functioning poorly. Very likely this is the immediate results of the constitutional disturbance—the systemic intoxication. In conclusion I may be permitted to express the opinion that hepatic complications are more common in syphilis than one is likely to infer from the literature on the subject. It is worthy of comment that the subject has not received the fulness of consideration that its importance would seem to warrant. I can not state how many cases have come under my observation, but the number is considerable; and in almost every instance the cases have been classified as either cirrhosis of the liver or carcinoma. When one finds cases in which there is a large accumulation of ascetic fluid, it is natural to make the mistake of considering the disease to be simple cirrhosis; but it would seem to be possible to make the differentiation in at least a great majority of cases.

DISCUSSION.

DR. WILLIAM OSLER, Baltimore—I congratulate the Section on the paper read not only on account of its intrinsic importance but on the emphasis laid on a subject of very special interest. I feel sure that visceral syphilis is much more common than the text-books or journals state, or than the general practitioner is willing to admit; not that it is any credit to the general practitioner that visceral syphilis is so common. It is a disease for the general practitioner and not for the specialist. The specialist rarely treats syphilis properly, i. e., thoroughly, and that is the task of the general practitioner.

Take the records showing the incidence of cerebral syphilis; the general practitioner says he has not seen a case of cerebral syphilis for ten years; he means, he has not recognized it. In reality, cases of brain and of visceral syphilis are very common, and the frequency means that the patients have not been systematically and thoroughly treated at the outset of the disease. With reference to diseases of the liver due to syphilis, my personal experience leads me to group them in four classes of cases:

1. Syphilis of the liver of congenital type. Formerly I used to see in infants diffuse syphilitic hepatitis of this type frequently enough; but now, as a clinical physician, I see few cases in young persons. These cases are almost always overlooked. It is to be borne in mind that syphilis of the liver of congenital type may occur as a late manifestation. One of the cases I saw was a boy of 11 years; the other a girl of 21 years.

2. In the adult, in this group of cases the patient comes before you with signs of ordinary cirrhosis of the liver, usually an adult man, a hard worker, a hard drinker, who gives a history of taking beer or alcohol. He presents the typical appearances of cirrhosis of the liver, i. e., jaundice, watery eyes, beginning ascites, enlarged smooth tender liver; it does not enter your mind for a minute that the man has syphilis of the liver. He is treated, perhaps purged; the ascites may disappear, but the patient leaves the hospital in the same condition as he entered and the diagnosis is made of cirrhosis of the liver. Yet this patient may return with the liver still enlarged, smooth and with the diagnosis of syphilis written on his back or on his shins in a well-marked syphilitic rash. These cases of syphilis of the liver that present the picture of cirrhosis may be difficult to recognize as syphilitic, yes, even impossible.

3. The third group of cases is more easily recognized because in addition to the cirrhosis there is tumor of the liver, i. e., an irregular liver with ascites and other signs of cirrhosis with often a slight jaundice. The liver may be small. The patient may be tapped three or four times under the supposition that he has to deal with cirrhosis of the liver. Under the influence of the iodids and mercury the ascites may disappear. I feel convinced that a certain number of cases of this type are supposed to be recoveries from cirrhosis of the liver. It should be remembered that Nature heals many of these cases. At the postmortem we know that there are found a large number of healed gummata which were not recognized during life.

4. There is a fourth group of cases occurring in the adult, to which Dr. Stockton has referred, namely, the solitary or multiple syphilitic tumors of the liver, without signs of ascites or enlargement, or at least, a great deal of enlargement, of the liver. There may be multiple or single tumors of the liver. Dr. Miller of Philadelphia reported a case in which the tumor was as large as the two fists on the surface of, and the back of, the liver; it lifted the whole surface of the abdomen. The patient was a robust man, in good health, with no impairment of the general nutrition. That tumor melted away completely under the use of mercury and the iodids. In this group the diagnosis may be made of carcinoma. I have recently seen an interesting case in which there was a distinct tumor of the left lobe of the liver, not very large, with stomach symptoms, pain, etc. This patient lost 25 pounds in weight; he became pale and anemic. At first glance it was thought he had a cancer of the stomach. Remembering other similar cases I inquired into a syphilitic history and found that he had had syphilis. I sent him into the hospital and antisiphilitic treatment was employed; within two months he gained 15 pounds in weight, and the anemia disappeared. Two months and a half after I first examined the tumor it had almost entirely disappeared. I have no doubt but that the case was one of syphilis of the liver.

DR. J. A. WITHERSPOON, Nashville, Tenn.—I have no doubt but that there are many cases of syphilis of the liver and visceral syphilis which are overlooked; I have no doubt that we all have overlooked them at times. I was very much impressed with one statement made, the similarity frequently noticed between enlargements, especially nodular enlargements, of the liver and malignant growths. I have more than once in my experience seen cases in which I felt confident it was of cancerous nature, which afterwards yielded under the use

of specific treatment. The patient's history will simulate that of cancer very closely and the condition of anemia which develops, with the loss of weight, simulates very closely cancer. I have repeatedly seen cases of acute hepatitis, syphilitic hepatitis, occurring in the eruptive period of syphilis; but I have never seen but a moderate enlargement in the early stages of syphilis, the enlargement coming on gradually and insidiously, with deep aching sensations in the region of the right hypochondrium, with progressive loss of flesh, with or without jaundice in the later stages. I have never seen a case of syphilis in which the liver reached a large size without the development of more or less ascites. I remember a case recently seen in which the ascites was so great that it was impossible to outline the liver at all and tapping the abdomen was the only means by which one could palpate the liver. To my surprise, after drawing off all the fluid, I found the liver extending down to the umbilicus. I remember one case which caused me some trouble in diagnosing between a gummatous mass and an enlarged gall bladder; I was in serious doubt whether it was the gall bladder or simply a localized enlargement from the right lobe of the liver.

There is another class of cases that I have seen in which the enlargement of the liver, with some dropsical effusion, was followed by obstruction of the bowel. A surgeon was called in and found by operation a very thick peritoneum and the obstruction was due to a coil of intestines dropping through a band of adhesions. This was removed and the patient recovered, but only after a long course of mercurial inunctions was the recovery complete. This case impressed me considerably; he had a distinct history of syphilis and he had been under treatment and there was no doubt that the primary cause of his trouble was syphilis producing the adhesive band.

So far as the use of iodids and mercurials are concerned I want to say that I have never gotten good results in visceral syphilis by the use of iodid of potassium alone. I have tried it in 20-grain doses, as mentioned by Dr. Stockton, and I have used it in enormous doses without any lessening of the size of the liver. But in the hypertrophic stage it will yield to mercurial inunctions. There is one class of liver syphilis which will not yield to any treatment, that class of cases mentioned by Dr. Stockton in which there is a contraction of the liver. In an enlarged liver with distinct syphilitic involvement, with the glandular enlargement, anemia, etc., these symptoms will disappear under proper treatment, but the indurated liver will remain as before. In this class we find the rigid valley and hills on the liver surface and I have never seen any good result from the antisyphilitic treatment employed. We should not expect it after fibrous contraction has taken place.

One of the largest livers I have ever seen was a syphilitic one and it is wonderful how long a time a child, with evident inherited syphilis, will carry such an enlarged liver without apparent symptoms developing other than those of a general malnutrition. I remember one case, a child one year old, in which the liver reached to the umbilicus. Without a history of syphilis I did not feel that I was warranted in calling it of syphilitic origin. It was associated with general anemia, snuffles, attenuated body; the child developed quite a lot of little eruptions, more like macules, which I attributed to a disordered stomach. What it was I did not know. Under mercurial inunctions there was a remarkably quick recovery.

I should like to refer to one other point in carrying the mercurial inunctions too far in the treatment of syphilis. While the local lesions may improve the systemic condition may become very alarming, the blood count dropping, and I have had to stop the antisyphilitic treatment and place the patient on general restoratives temporarily and then return to specific treatment.

I have seen but a few cases of visceral syphilis, recognized as such, that did not have marked constitutional manifestations to guide us. There is one symptom which invariably brings about some doubt, especially in my country where we regard every fever lasting a few weeks as suspicious of malarial poison, and that is fever. In a syphilitic subject you will find, with the fever, localized tenderness or soreness. I saw one case occurring in a woman in which the retroperitoneal or mesen-

teric glands were enormously enlarged; because the cervical and axillary glands were also enlarged, and because there was a great deal of anemia, I regarded at first the case as one of Hodgkin's disease, and the rise in temperature was considered to be that which occurs in this disease. I gave an unfavorable prognosis and placed the patient on arsenic and tried my best to ease the pathway to the other side. The patient went on, was better and worse, and finally went to the house of a practitioner who afterward told me that whenever he had a case the true nature of which he did not know he placed the patient on antisyphilitic treatment. He treated this patient in this manner and she is now enjoying good health. I saw the patient a few months ago and she looked like a different woman. I made the mistake when I looked for something rare and so I let her slip through my hands. Gentlemen, I think it is a good plan in cases of suspected syphilis to try specifics; this is especially advisable in that large type of cases referred to by Dr. Osler as cerebral, which manifests itself in more ways than any disease in my knowledge. When I find a case with peculiar symptoms, which point to the nervous system, I do not hesitate to try the antisyphilitic treatment, if I can not exclude syphilis or make a diagnosis, which is impossible in a great many cases.

DR. RICHARD C. CABOT, Boston—I will mention three points: 1. I should like to reiterate what Dr. Witherspoon has stated, namely, that in some cases it is for a time impossible to affect visceral syphilis by antisyphilitic treatment. Two soldiers of the Spanish war came to me affected with syphilis, with a perfectly clear diagnosis, the lesions affecting various organs. Antisyphilitic treatment was vigorously followed without the slightest effect. Measures were then adopted for building up the general health, and, after that had been accomplished the antisyphilitic treatment was effective.

2. I believe it is possible to mistake uremic hemiplegia for cerebral syphilis. I can recall a patient who gave a history of syphilis, with cerebral symptoms and signs, corresponding to what we would expect in cerebral syphilis: hemiplegia with gradual onset, followed by loss of consciousness. A diagnosis of cerebral syphilis was made. The man died and at autopsy a perfectly normal brain was found. There was then noted a glomerular nephritis. It was a case of uremic hemiplegia.

3. With regard to the diagnosis of syphilis, a year or two ago I made studies of the blood in syphilis and tried to verify the findings of Justus, who thought that he obtained in the blood of syphilitics, a characteristic reaction, a great decrease in the amount of hemoglobin after mercurial inunctions. Further investigations have convinced me that the method employed by him was unreliable.

DR. H. B. FAVILL, Chicago—The arraignment by Dr. Osler of the general profession for its remissness in detecting syphilis as a cause of various conditions opens to me a train of reflection. It is true that a great deal of visceral syphilis is misinterpreted. This is, of course, in large part due to the lack of knowledge of the possible facts on the part of physicians. Assuming, however, a proper pathologic conception of the process, on what lines are the conclusions to be laid down? In most instances there is great indefiniteness in the symptomatology and the discriminating man hesitates to adopt as a certainty a hypothesis that has a foundation so inconclusive even though probable. Is it not true that in the majority of the cases of visceral syphilis the diagnosis is reached by exclusion? This presupposes an attitude of mind with regard to the subject that is never oblivious of the possibilities in that direction, yet for the completion of the diagnosis there is necessary to the fullest extent the capacity to weigh and reject alternative views even more than an ability to recognize the earmarks of syphilis. Herein lies the gist of this subject as I see it. It must be admitted, however, that in a very large number of cases the diagnosis is not satisfactorily reached until after the therapeutic test. A recital of experiences by men of such broad experience as Drs. Stockton and Osler will show beyond a doubt that much of their procedure has been based on suspicion subsequently verified by response to treatment. In this there is a note of great encouragement to us of less confidence in the subject, for it is clear that the solution of the matter is to a large extent the constant bearing in mind

of that possibility, with an especial determination not to be swayed by negative history.

There is a phase of this subject not touched on in this discussion, namely, morbid visceral function in those of undoubted syphilitic antecedents, unassociated with anatomic lesions as we now know them. Is there a syphilitic physiology that is susceptible of recognition? Without going into that subject, I wish merely to call attention to the peculiarities of visceral function in children of syphilitic parentage who have none of the obvious signs of inherited disease. I think the experience of those who have investigated that aspect of the disease will accord with mine that there is much to be suspected in that direction. Of all phases of the subject this is the most distinctly dependent on the therapeutic test, which, though open to obvious objections, is not to be despised.

DR. M. H. FUSSELL, Philadelphia—I should like to call attention to one point not touched on by the writer of the paper, i. e., the absolute unreliability of the negative history of syphilis in cases with visceral manifestations; repeatedly have I seen cases of unquestioned visceral syphilis, which responded to antisyphilitic treatment, in which I could not obtain any primary or secondary syphilitic symptoms. With many the reason is that they are careless in their observations of the body and these patients do not have their attention called to their bodies until something hurts. An instance occurred recently in a man with a typical sore throat. I asked him if he had any rash on his body, and he answered, "No, there never has been." On being stripped, however, there was found a typical syphilitic roseola; the patient had been absolutely ignorant of its presence. Within the past few years I have had two cases of visceral syphilis occurring in infants in which I have used inunctions of mercury and iodid of potassium in addition, one grain three times a day; one patient died of an enterocolitis. I should like to ask if this was a coincidence, or the result of the iodid administered.

DR. C. F. HOOVER, Cleveland—I should like to say a few words regarding visceral syphilis. Some ten years ago I was much impressed by an autopsy on an American medical student who was supposed to be suffering from galloping consumption. He was under the care of Professor Nothnagel, who sent him to Switzerland where he did not improve. The cause of his death proved to be syphilis and not consumption. Since then I have looked for visceral syphilis and have been afraid of sending cases with syphilis of the lungs to Colorado. I have seen two cases of syphilis of the lungs, one beyond a question of doubt. This was a young man, who gave a clear history of syphilis, who had a marked dulness at the base of both lungs, expectoration of blood, temperature, night-sweats, loss of weight and other signs quite characteristic of tuberculosis, but an examination of the sputum revealed no tubercle bacilli. Antitubercular treatment failed to give relief, but iodid of potassium caused the fever to cease and, two months later, no evidence was to be found in the lungs and the patient is well to-day. Another man came under my observation with syphilis of the liver and spleen, with evidences of older gummata over the region of the sternum and clavicle and the physical signs of infiltration at the apex of the right lung. The man was unquestionably a syphilitic and, under anti-syphilitic treatment, all the physical signs, the dulness and râles, disappeared within a few weeks. Visceral syphilis occurs, in the vast majority of cases, in the liver and then occurs next in frequency in the spleen.

I should like to refer to one point in the treatment of these syphilitic cases. I think that from the discussion of the subject one may be misled; the impression that I have gotten so far is that, in all cases, no therapeutic result will be obtained in marked instances of retraction and lobulation. I remember several instances where the patient was under anti-syphilitic treatment, and still the fluid reaccumulated. To illustrate the point: one patient had serum in the abdominal cavity and remained in the hospital six months. His spleen was enormous. A diagnosis of syphilis was made. Iodids and mercurial inunctions were given without the slightest effect. The serum reaccumulated and he was tapped twice a week and then three times a week, then three or four times a

day, drawing off four or five quarts of serum. On the day following the tapping the abdomen would again be filled with serum. At last he had a profuse hemorrhage from the bowels and died. The autopsy showed the abdominal cavity dry. It seems that he was pumping a big wave of blood serum which contained no erythrocytes.

DR. THOMAS McCRAE, Baltimore—In answer to the question as to the treatment of solitary tumors of the liver due to syphilis, the patients referred to by Dr. Osler were placed on potassium iodid and mercurial inunctions; the iodid was given in 20-grain doses three times a day for six months. In the last case referred to by Dr. Osler improvement followed in five weeks.

DR. JAMES J. WALSH, New York—Since mercury is so prompt and effective in its action on syphilitic lesions, it is unfortunate that opportunities for its successful employment should sometimes be missed. Undoubtedly there are many cases of visceral syphilis in this country the diagnosis of which is missed entirely. It can not be too much insisted on that the absence of syphilitic history must not be accepted as an absolute guide in this matter. Syphilitic cirrhosis of the liver is without doubt sometimes treated as alcoholic cirrhosis. I have myself seen one case within a year in which a patient had been tapped several times for an ascites presumed to be of alcoholic hepatic origin, but which was really due to a large gummatous liver. Mixed treatment did away with the necessity for further tapping. A certain number of fatal cases occur every year that would surely survive if the mixed treatment were properly employed. In obscure lesions of the viscera the rule adopted by the neurologists should be adopted also by the general practitioner. When degenerative changes exist for which no good reason can be assigned the patient is put on specific treatment even though there should be no syphilitic history. There will be no regret if this rule is followed. Secondary symptoms are often so light as to escape notice and a primary lesion may run a typical course without attracting attention. I have seen a physician with chancre on the finger that had existed for nearly two weeks without exciting his suspicions. Two years ago I saw a professor in one of our colleges who came because of a tumor apparently of the splenic flexure of the colon. It was thought to be malignant and one of the best surgeons in the country advised operation and gave a very bad prognosis. Despite the absence of syphilitic history the therapeutic test of the mixed treatment was employed and the patient began to improve almost immediately. The tumor decreased greatly in size. It is now two years and four months since he was given less than six months to live and though there are some remnants of the tumor still left he considers himself in good health.

DR. T. B. FUTCHER, Baltimore—There is one point which should be brought up which has a bearing on visceral syphilis, and that is the possibility of visceral syphilis, in a percentage of cases, being the cause of fever of obscure origin. Recently I recorded three cases of fever of syphilitic origin occurring in Dr. Osler's wards. Sidney Phillips, a number of years ago, reported an interesting case of intermittent fever occurring in a patient who had contracted syphilis eight years previously. For a period of eight months this patient had had fever which was clinically indistinguishable from the fever observed in malaria. It occurred every other day, with chills and sweating. No malarial parasites were found in the blood. Later it was found that the husband had had syphilis shortly before he was married and his wife had contracted the infection from him. The patient was placed on iodid of potassium and immediately the chills, fever and sweating subsided. The fever of late syphilis is generally of continuous type, or of the intermittent type already described. In one of the three cases I referred to, the patient did not know that he had had syphilis and came into the hospital with a continuous type of fever which lasted for some weeks. The case occurred before the days of the Widal test and it was regarded and treated as typhoid fever. When the temperature refused to go down under treatment a subsequent examination revealed the fact that there was slight thickening of the clavicles and some evidence of cirrhosis of the liver. It was suggested that possibly the fever might be of

syphilitic origin. Under antisyphilitic treatment the temperature returned to the normal in three or four days. I speak of this case because of its obscure origin, due probably in part to visceral syphilis. As Dr. Hoover has already mentioned, a good many of these cases may be mistaken for tuberculosis of the lungs. Some years ago Dr. Janeway read a paper in which he reported a number of cases of syphilitic fever which had been sent to the Adirondacks for treatment for tuberculosis of the lungs. On the administration of the antisyphilitic treatment the fever ceased and the patients soon recovered.

Dr. Strockton, in closing—I wish to express my pleasure in finding that the subject has such a widespread interest; I believed that it would be interesting and I have not been disappointed. Dr. Osler has referred to a case which closely resembled ordinary cirrhosis of the liver and which was with difficulty separated from and distinguished from simple cirrhosis. Some cases reported by me, occurring in adults, had ascites, jaundice and associated symptoms. Dr. Osler dwelt on the point of associated jaundice and ascites, but personally I find fewer cases of cirrhosis of the liver with jaundice. When I find a patient suffering from a liver condition that may be cirrhosis, with associated jaundice and cachexia, I feel that the patient probably has visceral syphilis and not simple cirrhosis of the liver. In other words, jaundice with evidences of cirrhosis leads me at least to the suspicion of syphilis.

Dr. Witherspoon has stated that he has rarely seen much enlargement of the liver without ascites as an accompanying symptom. There are cases of enlargement of the liver of syphilitic origin, without ascites, and these are not so very common if we exclude general syphilitic hepatitis. In syphilitic hepatitis we almost invariably have jaundice. Yet we here occasionally find large or small gummata scattered through the liver, but we may find a good deal of enlargement without accompanying ascites; it depends largely on where the gumma is located. I have to-day reported cases in which there were tumors without either ascites or jaundice, and in one of them the disease gave rise to an enlargement of the liver of considerable proportions. The Doctor is right in stating that there is one form of syphilis of the liver which can not be improved by treatment, and that is in those instances where the liver becomes contracted as a late result. Such cases may not be expected to improve for such a patient is to that extent without a liver; still, there may be a temporary improvement. I remember a colored man who had an enormous hepatic growth which was thought to be a gumma; although he improved under treatment, ultimately he died from the results of a contracted liver. I doubt very much whether cases of syphilis of the liver will improve under any general treatment, unless accompanied by antisyphilitic treatment; I have never seen a case that did so. In cases of syphilis with malaria or some other associated condition no good effect will be produced unless the antisyphilitic treatment be employed in conjunction with the other treatment. Without mercury and the iodids you are opposing a hopeless proposition; but, with the addition of such measures, and the association of general hygienic treatment, you have a favorable prognosis.

Dr. Favill has asked Dr. Osler how he treated a case of syphilis which resembled malignant growth, and I was surprised to hear the question. I do not see how he could treat it except by the iodids and mercury—by inunctions—by all the usual means. Visceral syphilis is not a rare condition, but is much more common than is supposed. I have been chagrined that so many of such cases escaped me in former years—those that I now am curing by antisyphilitic treatment.

Diagnosis versus Drugging.—In the fight which we have to wage incessantly against ignorance and quackery among the masses and follies of all sorts among the classes, *diagnosis*, not *drugging*, is our chief weapon of offense. Lack of systematic personal training in the methods of the recognition of disease leads to the misapplication of remedies, to long courses of treatment when treatment is useless, and so directly to that lack of confidence in our methods which is apt to place us in the eyes of the public on a level with empirics and quacks. —Osler.

AN ANALYSIS OF SEVENTY CASES OF GASTROPTOSIS.*

J. DUTTON STEELE, M.D.

INSTRUCTOR IN MEDICINE, UNIVERSITY OF PENNSYLVANIA.

AND

ALBERT P. FRANCINE, A.M., M.D.

ASSISTANT INSTRUCTOR IN MEDICINE, UNIVERSITY OF PENNSYLVANIA.
PHILADELPHIA.

It is the purpose of the present contribution to place on record the study of a number of cases of gastroptosis, to analyze them and to draw conclusions which will be statistically accurate in the light of our present knowledge of the condition. The view that gastroptosis is usually associated with downward displacement of the transverse colon and movability of one or both kidneys and more rarely of the liver, has long obtained, but if we except the paper of Arneil there has been wanting a collection of cases systematically studied on which to base definite conclusions.

The records from which our material has been drawn, except a few cases in our private practice, were taken from our service in the Medical Dispensary of the Hospital of the University of Pennsylvania in the past two years. Our conclusions are based on the study of seventy consecutive cases. The positions of the stomach and colon were determined after inflation with air, the kidneys examined for mobility, the recti muscles for separation and the gastric contents after a test meal. Our investigations included as well the condition of the blood and urine.

The authors have been particularly impressed by the frequency of gastroptosis in women in general, and especially in that class which present themselves at our dispensaries. In thirty-five consecutive cases of women applying with stomach symptoms of the flatulent type gastroptosis was found in all. We are of the opinion that gastroptosis and enteroptosis are much more common than is usually supposed, and that in a very large proportion of all women complaining of symptoms of gastric motor insufficiency the dominant factor is downward displacement of the pyloric end of the stomach.

The pathogenesis of splanchnoptosis has not been touched on, for, unfortunately, the clinical study of these cases sheds little light on this much-vexed question. As to the theory of a congenital or acquired diathesis predisposing to splanchnoptosis there can be but little doubt that women of weak muscular organization are predisposed to it, and are more easily affected by exciting causes, which have little or no effect on other individuals. The most common of these exciting causes is probably something that tends to constrict the thorax or upper abdomen or to increase the volume of the abdominal cavity. Perhaps the truest thing that can be said in this connection is, that different causes are potent in different cases, and it is not wise or necessary to try to formulate a theory that will apply in every instance.

Our series included all types of individuals. Not only women in middle life who had borne children and who showed a considerable degree of diastasis of the recti muscles, but also males and young nulliparous women whose abdominal walls were firm and where normal approximation of the recti existed.

POSITION OF THE STOMACH.

The stomach was first emptied by lavage and then inflated with air through the tube. As the organ is dis-

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. Frank A. Jones, George Dock and J. M. Anders.

tended it rises to the abdominal wall, and its outline can usually be plainly seen. By percussion and auscultation, however, its position and size are accurately determined and noted on a suitable diagram. In order to convey to the reader an approximate idea of the size and position of the stomach the authors have divided the distance between the umbilicus and ensiform, and the umbilicus and top of the symphysis, each into four equal divisions. The two principal areas thus subdivided are usually equal, and in persons of average stature are about five to six inches or twelve or fifteen centimeters in extent. While at the first glance this may appear somewhat confusing, practically it is not so, as it will be found that nearly all displaced stomachs will fall

position, slightly above and behind the apex of the heart, and the general curve of the displaced viscus has not inaptly been described by Kelling as resembling a fishhook (diagram of typical cases).

In a recent paper by Dr. Steele, the statement is made that in his list of cases there were several that showed displacement of the cardiac end, giving rise to the descensus in toto or hunting-horn shape described by Riegel. Further examination of these cases have convinced us that this was an error. While theoretically such displacement is possible, no instance of it appears in our list, which includes Dr. Steele's cases, and we feel that its occurrence must be very rare. The cases in which the error was made presented an extreme degree of pyloric

Fig. 1.—Position of normal stomach and large intestine. (Quain.)

into one or another of these positions without in any sense coercing natural boundaries to arbitrary lines. It may incidentally be said of the umbilicus, as of the nipple, that it is not a fixed point, but for practical purposes it is a fairly accurate landmark.

Following this plan it will be found that the upper and lower curvatures or borders of the stomach may in the vast majority of cases be spoken of as falling in the quarter, mid or three-quarter line or position above or below the umbilicus; and it may be stated that in the prevailing type of gastroptosis the umbilicus is found to be the center of a circle, formed by the dilatation of the pyloric end of the stomach with the upper and lower curvatures midway between the ensiform and symphysis respectively. The cardiac end remains in its normal

Fig. 2.—Case 31. Female, 27 years. Gastroptosis and enteroptosis. Pyloric dilatation.

dilatation in stomachs originally small, but careful examination has convinced us that the cardiac end was in its normal position. In our series of 70 cases the upper and lower curvatures in 26 were midway between the ensiform and umbilicus, and symphysis and umbilicus respectively; in 12 the upper curvature was in the quarter position above, with the lower curvature midway below; in 9 the upper curvature was in the three-quarter position above, with the lower curvature midway below; in 7 the upper curvature was midway, the lower curvature in the quarter position below; in 5 the upper curvature occupied the three-quarter position above, the lower curvature the one-quarter position below; in 3 the upper curvature was in the one-quarter position above, with the lower curv-

ature in the three-quarter position below; in 2 the upper curvature was midway, with the lower curvature in the three-quarter position below; in 2 cases the upper curvature was at the ensiform and the lower curvature was midway between the umbilicus and symphysis; in 2 cases the upper curvature was at the umbilicus and the lower curvature midway; in 1 case the boundaries were at the ensiform and midway between the umbilicus and symphysis, and in 1 case the boundaries were in the one-quarter position above and below the umbilicus.

DILATATION OF THE STOMACH.

Some dilatation of the pyloric end of the stomach was present in every one of our series. The average de-

it may enter the third portion and thus on into the small intestine.

When the cardiac end of the stomach is enlarged as well we have considered the condition to be one of general gastrectasia. (Fig. 3.) Our investigations have convinced us that in a majority of cases general dilatation does not long exist without downward displacement of the pylorus, due to the dragging of the enlarged and over-weighted pyloric end on its supporting ligaments.

The proper etiologic relation of pyloric and general dilatation is probably correctly explained by saying that pyloric dilatation is secondary to a primary gastropotosis, while in general dilatation with gastropotosis the former is the primary factor.

Fig. 3.—Case 53. Male, 30 years. Gastropotosis and general dilatation. Enteropotosis.

Fig. 4.—Case 52. Female, 34 years. Gastropotosis and pyloric dilatation. Enteropotosis.

gree of enlargement is such that the outline of the pyloric extremity forms three-quarters of a circle, of which the center is the umbilicus. (Fig. 2.) It is conceivable that there may be a stage, very early in the course of primary gastropotosis, when pyloric dilatation is absent, but by the time the patient seeks medical advice such a condition is invariably present. This form of dilatation may readily be accounted for by the loss of muscular tone, stagnation and fermentation of the retained contents and the consequent distention. Another factor in its causation is the increased effort necessary on the part of the weakened muscle to force the food up and through the pylorus and the pro-lapsed first and second portion of the duodenum, so that

The comparison of the forms of dilatation occurring in the two sexes is of interest, since it shows that general dilatation in combination with downward displacement of the pylorus is more common in men, implying that gastropotosis in the male sex is due to primary dilatation in more than half the cases in which downward displacement of the pylorus exists.

Gastropotosis with pyloric dilatation alone occurred in 50 women and in 7 men.

Gastropotosis with general dilatation occurred in 2 women and in 10 men.

POSITION OF TRANSVERSE COLON AND FLEXURES.

The question of the position of the transverse colon, and more especially of the colonic flexures, is one of

considerable difficulty. We have examined the colon by inflation with air in thirty-six cases of our series. While we regard air inflation through the rectum as the best of the different methods so far devised, it is only in certain cases that a very definite idea can be obtained of the position of the large intestines. Unless the abdominal wall is thick or very rigid the sigmoid flexure, the transverse colon and the cecum may be seen and palpated when the bowel is inflated with air. In each percussion has been employed to confirm the results of inspection and palpation.

From the study of these cases the authors are of the opinion that in gastroptosis the transverse colon always shares in the downward displacement, and when filled with air occupies a position immediately below and in contact with the greater curvature.

The more difficult question is in regard to the hepatic and splenic flexures. The theory of Virchow and Glendard, that the hepatic flexure descends first, dragging after it the right half of the transverse colon, while the splenic flexure remains in place, is as difficult to substantiate as to disprove. The hepatic flexure lies more deeply than the transverse colon or the cecum, and while its upper limit is apparently fairly well defined by the upper limit of the tympany elicited in the right flank after inflation, we can not but feel that there is considerable room for error.

The splenic flexure lies behind the greater curvature and cardiac end of the stomach and eludes satisfactory demonstration. The accompanying Fig. 1, after Quain, shows the normal position of the colon, while in Fig. 3 the hepatic flexure is in a fairly normal position, and Fig. 4 illustrates the extreme limit of displacement observed in our cases. In our series we usually found downward displacement of the hepatic flexure, while the splenic flexure was lost on the opposite side of the abdomen usually 3 to 5 centimeters below the umbilicus, where it passed behind the greater curvature. In several cases the hepatic flexure was plainly as high as the costal margin. We believe that both the bowel and

stomach, when inflated, tend to assume a higher position than when empty and relaxed. Thus, in Cases 25 and 56, where the position of the viscera was determined at operation, the transverse colon lay fully a hand's breadth below the greater curvature, while the flexures were well above the umbilicus—although in all of our cases the colon, when inflated, followed closely the lower border of the stomach. It may well be that in many of such displacements the undistended transverse colon sinks much lower than the stomach, but when filled with air rides upward as well as forward to the abdominal wall and comes in contact with the greater curvature.

In Case 70 operation showed that the lesser curvature was midway between the umbilicus and pubis, although inflation indicated that the stomach occupied almost all of the epigastrium.

POSITION OF KIDNEYS, LIVER AND SPLEEN.

In our examination of the kidneys we have employed the bimanual method, in which the patient lies on the back with the thighs flexed on the abdomen and with the abdominal wall as relaxed as possible. One hand is placed over the lumbar region and the other is passed down, as far as possible, under the margin of the ribs. Palpation is made during both forced respiration and when the abdomen is in repose. In describing the degree of displacement we have adopted the following nomenclature. When the lower edge can be felt on deep palpation the kidney is said to be movable in the first degree. The term second degree is used when during a forced inspiration the finger tips can be slipped above the upper pole of the organ, but it can not be brought below the level of the navel. When the kidney can be pushed freely about in its own half of the abdomen, or even beyond the median line, the term third degree is applied. In 39 out of 64 cases, or 60.9 per cent., the right kidney could be palpated. In 18 of these it was barely palpable, in 12 it was movable in the second degree, and 9 cases were movable in the third. Both kidneys were movable in 4 cases. Ptc liver occurred 3 times and of

MOVABILITY AND PTOSIS OF KIDNEYS, LIVER AND SPLEEN.

Right Kidney Alone Movable.

Both third degree	1
Total	4

Total cases gastroptosis with ptosis of kidneys.. 39, or 60.9 p. c.

Total cases gastroptosis with ptosis of liver..... 4, or 5 p. c.

Total cases gastroptosis with ptosis of spleen.... 1, or 0.7 p. c.

CASE 54.—Operation showed a much enlarged liver, which was displaced downward and was abnormally movable. Gastroptosis and movable right kidney.

CASE 55.—There was great movability and displacement of both kidneys (third degree), liver and spleen.

CASE 56.—Operation showed that the liver was unduly movable and displaced downward.

CASE 70.—Operation showed a floating liver. Gastric ulcer of the lesser curvature.

Thus in 3 of 6 cases operated on the liver was unduly movable and sagging downward. As this is 50 per cent. of the cases operated on the idea strongly suggested itself that ptosis of the liver may elude our methods of physical examination and be more frequent than has been supposed.

NEURASTHENIA.

This associated taint which has played so conspicuous a rôle as to give rise to the theory of Charcot and Bouvert, that it was the cause of gastroptosis, was not very infrequent in our series. The tendency of later observers seems to be to place very little weight on neurasthenia as the primary cause of abdominal ptosis. In 48 cases it was present in 22, or 45.8 per cent. The difficulty in obtaining accurate data as to the presence or absence of neurasthenia in dispensary practice is considerable. While it may be present in the same degree in the class of patients who present themselves at our dispensaries as in those seen in private practice, it is certain that its manifestations are not so pronounced as in those more well to do and highly strung. It should also be borne in mind that in a brief acquaintance with a walking patient it is not always easy to make a diagnosis of neurasthenia.

In cases of gastroptosis suffering with various functional disorders of the nervous system, a distinction must be made between these symptoms and true neurasthenia. The fact that gastroptosis does occur in a large proportion of cases without neurasthenia disproves the theory that the two are interdependent. It is much more likely that when they coexist they are merely concurrent manifestation of some constitutional weakness, be it congenital or acquired.

ANALYSIS OF THE GASTRIC CONTENTS.

The condition of the gastric contents after the ingestion of an Ewald test meal was most frequently one of hypoacidity. A certain proportion were approximately normal and hyperacidity appears to be uncommon. Free hydrochloric acid was absent in 13 cases of 45 examined, or 29 per cent., and in 17 cases the free HCl was 10 or under. Thus in 66 per cent. the amount of free HCl was subnormal. In 9 cases the acid was approximately normal in amount. All of these were well-marked examples of the condition and of considerable

duration. The figures given are in terms of decinormal soda hydroxid solution.

Six cases showed hyperacidity. Of these Case 59, a young woman, and Case 68, a man aged 45, were instances of primary gastroptosis with a strong neurotic tendency. Cases 22, 35 and 53 were men in early adult life, all decidedly neurasthenic with downward displacement of the pylorus and a considerable degree of general dilatation. In Case 70 (a man aged 50) operation revealed a gastric ulcer. This was the only case with symptoms of organic lesion of the stomach. It will be seen that but two of the six cases with excess of hydrochloric acid were instances of primary gastroptosis.

TABLE OF HYDROCHLORIC ACID.

Free HCl absent.....	13; average total acidity, 16
Free HCl 10 and under....	17; average total acidity, 52
Free HCl 11 to 25.....	9; average total acidity, 47
Free HCl above 25	6; average total acidity, 80

SYMPTOMS.

In those cases in which the dilation affected the pyloric extremity alone the subjective symptoms were those of motor insufficiency of a mild grade. Evidence of fermentation, as manifested by gaseous eructation, coming on an hour or so after meals, were observed in every case. Some degree of autointoxication was almost as constantly present. Attacks of frontal headache, accompanied by nausea following fatigue or indiscretions in diet and which were relieved by treatment directed to the stomach, occurred in 20 per cent. Pain in the epigastrium or upper abdomen was complained of in 50 per cent. Its character varied, but was most often described as dragging, and was most intense an hour or so after meals. Pain in the lumbar region was present in 25 per cent., vomiting in 16 per cent., and nausea in 12 per cent. Constipation was the rule and was decided in character in 60 per cent. A small proportion of the rest suffered from alternating diarrhea and constipation, and in one or two diarrhea alone occurred, which was relieved by lavage and by medicinal measures directed to control the fermentation.

In the cases of general dilatation with gastroptosis, the signs of impairment of motor power were much more pronounced, and it was here that the only instances of decided retention occurred. Two of the cases of vomiting were in men with marked general dilatation. Evidences of autointoxication were much more intense in this class of patients.

It has seemed to us that in these cases displacement of the stomach was the dominant factor in the production of subjective symptoms. Signs of intestinal disturbance were not intense in any of our cases. The constipation and diarrhea were moderate and easily controlled. With the exception of those cases in which the kidney was floating the dislocation and movability of that organ did not give physical discomfort.

A floating tenth rib, the stigma described by Stiller, was noted in only two of our series.

THE SPLASHING SOUND.

Our experience with this sign, if properly used and elicited, is that it is of value in determining a decrease in power of the stomach muscle, when obtained during the period of digestion; and of motor insufficiency when obtained at a period when the stomach should have emptied itself into the duodenum. In studying the relations of the splashing sound to atony, the patient should be under observation for a longer time than a dispensary service allows, consequently we have not been able to obtain data of any value in this connection.

THE URINE.

The urine was negative so far as routine examination is concerned. The average specific gravity was not above normal, arguing against any considerable degree of concentration as seen in severe cases of gastric motor insufficiency.

SEPARATION OF THE RECTI ABDOMINALIS.

This important sign, described by Webster, was noted in 17 of 46 cases examined for it, i. e., in 37 per cent. The amount of separation varied considerably, in some instances being only sufficient to admit the finger tips, in others the width of three or even four fingers. The cases in which the condition was observed were all females, of whom 11 had borne children and 6 were nulliparous.

The following case is of interest since it emphasizes the difficulty of arriving at any definite conclusion as to the etiology of abdominal ptosis.

R. H. Female. 35 years of age. White. Has born 13 children. Presents such diastasis of the recti muscles that the whole fist can be inserted between them in the umbilical region. In spite of this very decided relaxation of her abdominal walls, inflation showed that her stomach was in its normal position. Her right kidney was movable in the second degree.

CONDITION OF THE BLOOD.

Meinert, in his original paper, held that chlorosis was the cause of gastroptosis, but his views were refuted by Kelling, who showed that the two conditions had no direct etiologic connection. Our series bears out this conclusion, for only one of our cases suffered with chlorosis, while in the greater portion of the remaining the blood was normal, and the rest showed but a slight secondary anemia. The high color index in the following table speaks for itself in excluding chlorosis.

COLOR INDEX OF THE BLOOD.

Hemoglobin, 85 p. c. or over 24.	Average color index, 0.95
Hemoglobin, 60 p. c. to 84 p. c. 20.	Average color index, 0.9
Hemoglobin, 35 p. c. 1.	Average color index, 0.5

TREATMENT.

Discussion of methods of treatment would be out of place in a paper of this character. The experience, however, obtained in the observation of the series reported has impressed us with several facts that seem worthy of mention. Relief from symptoms of motor insufficiency may often be obtained by mechanical support of the pylorus. This statement applies as well to cases of general as to those of pyloric dilatation.

Systematic lavage is not indicated when mechanical support is applied, provided there is not decided retention or great alteration in function of the gastric mucous membrane. We have found it of advantage only (1) in cases of extreme atony and general dilatation with much retention, and (2) in cases in which, without dilatation, there is an excessive secretion of mucus.

Six of our cases have been operated on. The results will be reported in detail by the gentlemen who performed the operations. It may be permitted us to make brief mention of the character of the procedure in each case:

CASE 25.—Ventral suspension of the uterus, approximation of the recti muscles in the lower half of the abdomen, nephrorrhaphy.

CASE 54.—Suspension of the liver.

CASE 56.—Shortening of the gastro-hepatic omentum. (Beyea's operation.)

CASE 49.—Nephrorrhaphy, stitching the pylorus to the hilum of the liver.

CASE 52.—Stitching the pylorus to the hilum of the liver.

CASE 70.—Excision of gastric ulcer.

CONDITION, AGE AND SEX.

In our series there were 52 women (70.4 per cent.) and 18 men (30.6 per cent.). Twenty-one of the women had borne children. It will be seen that 59 per cent. of the women were nulliparous. Very few of our dispensary cases are under 20 years of age. Consequently we have been unable to determine whether gastroptosis is frequent in childhood as claimed by Meinert. A great majority of our series came under observation while in the third, fourth and fifth decade. The youngest patient was a girl of 18 years, the oldest a man of 71.

TABLE OF AGES BY DECADES.

Under 20	1	51 to 60	3
20 to 30	24	61 to 70	1
31 to 40	18	Over 70	1
41 to 50	21		

CONCLUSIONS.

1. Gastroptosis is much more common than might be inferred from the meager reference made to it in a majority of the text-books on general medicine. In women showing symptoms of gastric atony its presence is almost constant. It is much less frequent in men.

2. The occurrence of gastroptosis is not confined to any particular age or class of individuals. There are no causative factors common to all cases, and no explanation of its etiology heretofore given is broad enough to be wholly satisfactory, if we except the theory of congenital predisposition, which is entirely hypothetical.

3. The position assumed by the stomach in all of our cases was vertical or subvertical. Total descent was not observed and probably is extremely rare. Some dilatation of the pyloric extremity was always present. When this dilatation affects the pyloric end alone it may perhaps safely be assumed that the dilatation is secondary to the descent of the pylorus. In general dilatation and gastroptosis it is probable that the displacement is secondary to the dilatation. The data in regard to the position of the stomach were obtained in every case by inflation with air through the stomach tube. The colon was inflated through the rectum.

4. The transverse colon invariably shared in the displacement, assumed the M or V shape, and when inflated by air was in close contact with the greater curvature of the stomach. The hepatic flexure may not be displaced or may sink to the level of the umbilicus. The splenic flexure lies behind the stomach and eludes demonstration.

5. The right kidney was movable in 60.9 per cent. of the cases. The left kidney rarely showed abnormal movability and the spleen in but one case. The fact that the liver was observed to be unduly movable and sagging downward in three of six cases operated on suggests that ptosis of this organ may elude our methods of physical examination and be more frequent than is usually supposed.

6. There is no condition of the gastric contents peculiar to gastroptosis. Absence or diminution of the free HCl is the rule. In a few cases the amount was normal. Hyperacidity was rare and usually occurred in cases where general dilatation existed, and when there was a strong neurotic taint.

7. There were no characteristic changes in the blood or urine.

8. The subjective symptoms were those of gastric motor insufficiency, and were of a mild grade in cases of primary ptosis, but more severe where general dilatation existed. Pain was present in the upper abdominal region in about half and in the lumbar region in a quarter of the cases.

9. The same causes that produce neurasthenia appear to favor the development of ptosis of the abdominal viscera. When the two conditions are established they probably react on each other deleteriously, but clinical evidence tends to contradict the theory previously widespread that they have a direct causative relation.

DISCUSSION.

DR. ALLEN A. JONES, Buffalo—This matter of gastroptosis is a very important one and has been very ably presented this afternoon. It has been my firm belief that many cases of this affection commence in early life, occurring particularly in those nervous, highly organized, restless children, with narrow thoraces, whose stomachs are filled most all the time, never empty except for one or two hours before breakfast. I speak here of the etiology of gastroptosis because our knowledge of it is so inadequate. In addition to the symptoms mentioned by Dr. Steele there are the circulatory ones, such as coldness of the hands, dizziness, vertigo, cerebral anemia and, as already pointed out, such disturbances as are due to disturbed circulation in the splanchnic area. In a paper read one year ago, but which I failed to publish, my conclusions were the same as others have given regarding the stomach in gastroptosis, that there is a delayed passage of food into the duodenum which is sometimes serious and leads to a dilatation. This dilatation occurs particularly toward the pyloric end of the stomach. Robinson of Chicago, not long ago, published a paper on this subject presenting the results of his studies and he made the statement that dilatation of the stomach in vicerptosis was due to the fact that the sheath of the superior mesenteric artery passing down over the duodenum made pressure on the duodenum and so caused a difficult onward passage of its contents causing dilatation of the stomach and duodenum. The results of a gastro-jejunostomy were admirable. In the consideration of enteroptosis the question of intra-abdominal pressure is important.

DR. CHARLES G. STOCKTON, Buffalo—I believe that this condition of splanchnoptosis is more common than is generally supposed, and that it plays a part in the production of the neurasthenia that we so often see in the lymphatic type of women. Dr. Steele is to be congratulated on the good results he has obtained by surgical methods. Splanchnoptosis is a disease peculiar to those who walk in the upright position, and is a disturbance to which quadrupeds are not subject. It is true that the visceral displacements in the abdomen are not, as a rule, dependent on contraction of scar tissue, nor from the unusual weight of the stomach and other organs, although such conditions do occasionally have an unfavorable effect. As a rule, splanchnoptosis develops in those who have unusually fragile tissues which are lacking in inherent strength. Surgeons have found, in attempting to produce fixation of displaced organs, that there is difficulty in finding a sufficiency of strong tissue through which sutures may be placed.

DR. BOARDMAN REED, Philadelphia—I wish to emphasize the great importance of making a correct diagnosis of this condition, for I am sure that it occurs in the practice of nearly every physician. Physicians should make a more careful examination of their patients in cases of obstinate constipation, neurasthenic disease, etc. As to the etiology of the trouble, it seems to me that not enough emphasis has been placed on the matter of dress. Dr. Jones has stated that he believes a great many of these instances arise in infancy; I have reached the same conclusion, for I have found the stomach as low as the umbilicus or lower in many young children. In women I frequently find the stomach as low down as it can go—in the pelvis, resting on the pelvic organs. The dress of women, especially the corset, favors the sinking of the stomach lower and lower, besides weakening the abdominal muscles by preventing exercise of them.

DR. FENTON B. TURCK, Chicago—There are several factors which may predispose to gastroptosis, and among them are the congenital conditions which Rosengert regards as reversion type, congenital deformity. There are certain predisposing factors which are more important than have been referred to to-day. I would especially emphasize the errors of living and disregard for personal hygiene early in life. The chief condition found associated is an atony of the stomach and a resulting toxemia. I have found that the filtered stomach contents withdrawn from the stomach in cases of gastroptosis with atony, when injected into animals, would show a greatly increased toxicity over normal stomach contents. The increase in the toxicity of the gastric contents is an important diagnos-

tic indication of the lack of motor power. The resulting increase of bacterial growth which causes the formation of toxins in the stomach is responsible for many of the symptoms. The abdominal belt does not lift the stomach at all, as has been shown by a careful examination with the gyromele in connection with the x-rays. The skiagraph shows no change in location of the stomach when taken before and after the adjustment of the belt. The improved condition after the application of the abdominal support is due to the increase in the intra-abdominal pressure which increases the blood pressure, overcoming the splanchnic congestion. This also benefits the tone of the gastrointestinal musculature. Dietetic treatment, rest in bed and appropriate abdominal exercises are of the highest therapeutic value in connection with other treatment which I shall soon refer to. The benefits of operations in these cases may be largely due to the prolonged rest in bed which follows the operation, something like the Mitchell rest-cure treatment. The indications for treatment are not simply mechanical, but call for an increase in the tone of the muscular contractions so as to favor the ready passage of food through the pyloric orifice of the stomach. If the pyloric orifice is narrowed, causing obstruction, gastroenterostomy is indicated. I would emphasize the fact that we should endeavor to improve the splanchnic circulation, distribution of blood to the surface of the body. An increased elimination will result. If we should find that by the abdominal displacement there resulted kinking of the duodenum and obstruction, then I think an operation is rational. The most frequent pathologic condition in these cases of gastroptosis is lack of motor power of the stomach, due to atony, and if a dilatation occurs, it is usually a result of the atony. The low blood pressure, cold hands and feet, showing peripheral contraction of the arterioles, accounts for many of the neurasthenic symptoms, but we must admit that neurasthenia may act as a cause of gastroptosis, as well as the result. It is a significant fact that when atony of the stomach is overcome, and the disturbance of circulation restored, the neurasthenic symptoms disappear. Disturbance of the splanchnic circulation is undoubtedly an important factor in the production, as well as the result of gastroptosis. So long as this condition exists, it interferes with the nutrition, and the lax condition resulting favors the downward displacement. The indications for treatment of gastroptosis, then, are: 1, increase the peristaltic activity of the stomach. This prevents the toxic condition; 2, restore the splanchnic circulation by reducing the congestion of the abdominal vessels; 3, increase the strength of the abdominal walls. This is accomplished chiefly by suitable abdominal exercises; 4, operation. In some cases this may be the only plan that can be adopted with any chance of success. The use of pneumatic gymnastics of the stomach, as employed in Chicago, I think of great value. In stomach gymnastics it has been found that when compressed air is introduced into the stomach through a tube and then allowed to escape (repeating this several times in succession) it causes a compensatory hypertrophy of the muscular walls of the stomach. Air distends the organ uniformly in all directions. It is compressible, and, while it stretches the stomach walls, it permits contraction of the stomach muscles, isometric contractions resulting. Peristalsis is increased by this method without fatigue. The air can be heated before it is introduced by passing it through water at a temperature of 55 C. (131 F.). It passes through the afferent canal of the double tube, distends the entire stomach, the circulation is stimulated by the heat and the air passes out through the efferent canal of the double tube. As a supplementary method of exercise to the abdominal viscera, I have found my exerciser of great benefit. This is an extension exercise for the abdominal muscles. The very best abdominal support is strong abdominal muscles.

DR. FRANK BILLINGS, Chicago—There is no doubt that many cases of ptosis of the stomach and colon are congenital. As time goes on more cases are found on account of the dress of woman, and more cases are seen in women than in men. In many cases of the disease, until something of a general kind occurs, such as a neurasthenia, the patients do not feel anything abnormal. The point that I wish to make is that the

neurasthenia is primary, in many cases producing general myasthenia. Not until the muscular power of the stomach fails, from general causes, does the patient suffer.

Dr. J. DUTTON STEELE, Philadelphia—I agree with everything that has been stated with regard to the etiology. I can not take issue with what Dr. Turk has stated for I have never been able to see how gastric motor insufficiency from gastroparesis is different from an insufficiency from any other cause. I think it is very important that every physician should outline the stomach in all patients who come to him with symptoms of such a condition. It may influence the kind of treatment employed.

THE PURSE-STRING SUTURE IN GASTRORRHAPHY FOR GUNSHOT WOUNDS.—AN EXPERIMENTAL CONTRIBUTION.*

N. SENN, M.D., PH.D., LL.D., C.M.

Professor of Surgery, Rush Medical College, in Affiliation with the University of Chicago.

CHICAGO.

One of the important elements of success in the treatment of gunshot and stab wounds of the stomach is time. Unnecessary time lost in finding and suturing the visceral wounds is a source of immediate danger to life which should be eliminated as far as possible by means which enable the surgeon to make a quick and correct diagnosis and by resorting to a method of suturing which closes the wound safely and securely with the least possible delay and which leaves it in a condition most favorable for speedy definitive healing. It is well known that small penetrating wounds of the stomach often heal without operative intervention. By contraction and relative displacement of the different muscular layers of the thick wall of the stomach the tubular wound is contracted and obstructed sufficiently to prevent leakage until the canal on the peritoneal side becomes hermetically sealed by firm plastic adhesives which prevent extravasation during the time required for the repair of the visceral wound. If in larger wounds of the stomach the same degree of occlusion can be accomplished by the simplest mechanical means then such a procedure should take the place of the more time-consuming methods of suturing now in general use. This can be accomplished with the purse-string suture. (To Dr. Dawbarn of New York belongs the credit of having first suggested the use of the purse-string suture in the treatment of small perforations of the gastrointestinal canal.)

In gunshot injuries the defect in the stomach wall is circular, the wound margins contused, hence the deep sutures could at best furnish a barrier to the escape of stomach contents only for a short time, as their hold in the necrosed tissues would be imperfect and only of brief duration. In small, round wounds the circular suture is the one which will bring and hold together in permanent, uninterrupted contact the serous surfaces in the most efficient manner. In the treatment of gunshot wounds of the stomach the principal object of suturing should be to close the perforation in such a way as to guard securely against extravasation and at the same time approximate and hold in apposition a maximum surface of intact healthy peritoneum. This is accomplished by making a cone of the injured part of the stomach with the apex corresponding with the wound directed toward the lumen of the organ. The purse-string suture applied in a manner that will be described in the experimental part of this paper, will maintain this cone until the healing of the visceral

wound has advanced sufficiently to render further mechanical support superfluous. The cone on the mucous side of the stomach acts in the manner of a valve, which in itself is an effective barrier against the escape of stomach contents, while the circular suture constitutes almost an absolute safeguard against leakage and brings in contact the serous surfaces in the interior of the cone. For wounds of the posterior wall of the stomach I recommend a purse-string suture of heavy durable catgut to be applied through the anterior wound. The anterior wound is closed with a purse-string suture of silk of medium size applied to the base of the cone on the serous side. It is desirable that the circular suture should cause no necrosis of the included tissues. By using an absorbable suture in closing the posterior wound in the interior of the stomach this object is gained, as only a small part of the thickness of the stomach wall is subjected to pressure, and the tension caused by the ligature is gradually lessened by softening of its material and is entirely removed by the absorption and digestion of the ligature in less than three weeks.

The wound of the posterior wall of the stomach is

Fig. 1.—Case 4. Showing irrigation of bursa omentalis through the opening in the posterior wall of the stomach.

found and made accessible by inserting through the anterior wound a grasping forceps with which the posterior wall is seized at a point where, from the course of the bullet, the second wound is supposed to be located. Through a wound large enough to admit the index finger the greater part of the posterior wall of the stomach can be made accessible to sight and touch, and the perforation can be located and closed with the purse-string suture in a few moments. In doubtful cases inflation of the stomach should invariably be practiced for the detection of a second and possibly a third perforation.

EXPERIMENTS.

The following experiments were made for the purpose of demonstrating the practical utility of the purse-string suture in the treatment of perforating wounds of the stomach.

CASE 1.—Dec. 23, 1901, a white and brown medium-sized male dog was chloroformed and through a median incision three inches in length the anterior surface of the stomach was exposed and brought forward into the wound. A vertical visceral incision was made an inch in length about one inch above the curvature and half-way between the cardiac and

* Presented to the Surgical Section of the British Medical Association Manchester, July 30, 1902

pyloric ends. Through this opening the posterior wall was seized with a forceps and drawn into the wound in the form of a cone. Around the base of this cone a purse-string catgut No. 3 ligature was applied, taking four seizures which included all the tunics except the peritoneum. The apex of the cone was then amputated, making a perforation large enough to insert the tip of the little finger. The anterior wound was next closed by taking five seizures half an inch from the wound margins with a needle armed with medium-sized silk which included all of the coats except the mucous membrane. Before the circular suture was tied the margins of the wound were deeply inverted in order to secure apposition of large serous surfaces. The abdominal incision was closed with four deep silk sutures and three superficial sutures of fine silk and the wound sealed with collodion. The dog was fed as usual,

Fig. 2.—Case 4 Purse-string silk suture in place

took his food with a relish and at no time manifested any untoward symptoms.

Postmortem.—The dog was killed five days later, when the following conditions were found: External wound firmly united, no peritonitis. Anterior wound of stomach healed, a narrow strip of omentum adherent over the encysted silk purse-string suture. Posterior wall of stomach free and wound healed. On opening the stomach small granulating points indicated the location of the wounds.

CASE 2.—Small brown poodle dog. Operation the same as in the preceding case only with this difference, that the wound in the posterior wall made by the circular excision was large

Fig. 3.—Showing result of purse string silk suture closing anterior wound in stomach wall.

enough to insert three fingers; consequently, more seizures were made in applying the catgut purse-string suture, and the ligature was applied after the wound was made. Before tying the ligature the peritoneum of the wound margin was seized with forceps at two opposite points and traction made so as to include as much as possible of it in the grasp of the circular suture. In applying the anterior suture the seizures, four in number, were taken three-quarters of an inch from the margins of the visceral incision and with forceps the peritoneum was pushed as far as possible in the direction of the cavity of the stomach with the same object in view. The dog recovered without any untoward symptoms notwithstanding he was fed on the coarsest kind of food from the time of operation until he was killed, twenty days later.

Postmortem.—External wound firmly united. Firm adhesion over a point corresponding with the location of the underlying encysted silk suture. Posterior wound healed perfectly without any external adhesions. The stomach was removed and opened at the lesser curvature. The mucous membrane over the entire surface of the stomach was normal and it was exceedingly difficult to locate the minute scars in its folds. The catgut ligature had disappeared and the cone was reduced to the level of the surrounding mucous membrane. The silk ligature was firmly encapsulated.

CASE 3.—Small black bitch. Anterior and posterior wounds were made before the ligatures were applied. The external incision was closed by six deep silk sutures and sealed as usual with collodion. The experiment was made January 3 and the dog killed on the 31st with chloroform.

Postmortem.—Anterior surface of the stomach smooth and only a very circumscribed omental adhesion over the silk suture. The stomach was removed and no mark could be discovered on the posterior surface to indicate the location of the perforation. On opening the stomach the exact location of the anterior wound could only be determined by a circumscribed thickening of the wall, covered by normal mucous membrane, which was thrown into radiate minute folds the center of which corresponded with the exact location of the wound. The posterior wound healed in the same ideal manner.

CASE 4.—Small brown male dog. In this experiment the feasibility of flushing the retrogastric space was demonstrated after making wounds in the anterior and posterior walls of the stomach as large as wounds inflicted by large-caliber bullets. The nozzle of the irrigator was firmly fixed in the posterior wound by tying the purse-string in the form of a loop over it (as shown in the illustration). After the irrigation the nozzle was removed and the suture tied in the usual manner. Anterior wound closed with circular silk suture. The dog was killed four weeks later.

Postmortem.—Findings the same as in the preceding experiment.

REMARKS.

The above experiments demonstrate the safety of the circular suture in the treatment of gunshot and other penetrating wounds of the stomach. All of the animals operated on in this manner recovered, and the repair of the injuries as shown by the specimens was ideal. The absence of adhesions over the posterior wound and their constant presence over the anterior wound indicate that the presence of the silk ligature and the needle punctures were the causes of the circumscribed plastic peritonitis which produced them. In none of the specimens could any indications be found of necrosis of any of the inverted tissues and included in part by the circular suture.

In the course of three weeks the continuity of the mucosa at the seat of the injury was completely restored. The result of these experiments have convinced me that the circular suture compares favorably with the methods of suturing in general use and besides has the great advantages over them in the ease of its application and the saving of much valuable time.

Suturing of the posterior wound by partial eversion of the stomach through the anterior obviates unnecessary handling of the organ, and the necessity of interfering with the vascular supply incident to exposure of the posterior wound as is done by the methods now generally practiced. If extravasation into the lesser peritoneal cavity has taken place, flushing through the posterior wound and a vertical slit in the gastrocolic ligament and gauze drainage through the latter are invariably indicated.

When a urinary antiseptic is needed try lithium benzoate. It is eliminated through the kidneys, increases the flow of urine and sedates the urinary tract.

THE PURPOSES OF URETER-CATHETERISM— PRESENTATION OF URETER-CYSTOSCOPE FOR MALE AND FEMALE.*

BRANSFORD LEWIS, M.D.

Professor of Genito-Urinary Surgery, Marlon-Sims-Beaumont Medical College; Genito-Urinary Surgeon to Rebekah Hospital, to City Hospital, Female Hospital, etc.

ST. LOUIS.

The purposes of ureter-catheterism in connection with the cystoscope are twofold: For diagnosis and for treatment.

DIAGNOSIS.

A. To locate the origin of pus, blood, tubercular products or bacilli, the various pyogenic infections, abnormally desquamated epithelium, etc., as to whether they come from (a) the bladder, (b) the right ureter, (c) the left ureter, (d) the right kidney (e) the left kidney, (f) the right or (g) the left peri-renal space and communicating with the corresponding kidney or ureter.

B. To recognize and locate obstructive conditions in the right or left ureter, from (a) stricture, (b) stone, (c) adjacent tumors, (d) bend or kink in the ureter from movable or dislocated kidney, (e) valvular junction of ureter and pelvis.

C. To determine (a) the presence of two kidneys, (b) if only one, which is absent.

D. To determine the number of ureters present.

E. To determine the functional activity of each kidney separately and relatively, with respect to its excretion of urea, albumin, quantity of urine, the specific gravity, etc.

F. To determine the size and capacity of each kidney-pelvis, with respect to (a) hydronephrosis, (b) pyonephrosis, (c) total obliteration of secreting kidney tissue.

G. If there be kidney disease present, to determine (a) if only one kidney is affected or both, (b) if only one, which is the affected one, (c) if both, which is the one more affected, (d) if removal of the worse one be advisable, is the other able to carry on kidney function sufficiently; (e) if removal of one be advisable, and the other is capable of supporting life, will the operation remove the infection from the body, removing possibility of dissemination or recontamination?

TREATMENT.

A. To enlarge narrowings or strictures at (a) the ureter openings, or (b) in the channel of the ureters. By facilitating drainage through the increased ureter caliber, thus obtained, to assist in the improvement of pyelitis, or pyonephrosis, unilateral or bilateral.

B. To irrigate and medicate (a) the ureters; (b) the kidney pelvis of one or both sides.

C. To assist, by anesthetizing and enlarging the ureter opening, the passage through it of a calculus or a plug of pus, blood, etc.

To accomplish the purposes above described one must have an instrument that effects ureter catheterization easily and quickly without causing trouble to the patient or bad after-effects. I believe I have accomplished this result in the ureter-cystoscopes for male and female which I herewith present. The instrument consists, as you see, of a straight tube through which one looks directly at the object without the intervention of lenses and without the accompaniments of refraction, absorption of light, etc. The illumination is made by a cold electric lamp, which allows the use of the cystoscope

in the bladder without introducing water and without burning the patient. This obviates the difficulties coming from the clouding of water, since air is used for distending the bladder. Air, of course, can not be clouded by the inflowing of blood or pus in ways that destroy the transparency of a liquid vehicle.

With cocain anesthesia the process of ureter catheterization is easily accomplished in either the male or the female with this instrument. I have used it upwards of three dozen times this spring, mostly in my office, allowing the patients to get up and leave immediately afterward and go about their business.

It has enabled me to accomplish something else which I believe will be very valuable in cases of pyelitis: that is, washing out the kidney pelvis in chronic inflammation of that organ, either unilateral or bilateral. I have done it in both the male and the female in a number of instances. In three cases which were the subject of chronic unilateral pyelitis I washed out the affected kidney pelvis with marked improvement and no detriment.

The advantages in favor of ureter-catheterism as compared with segregation are very great. In the matter of diagnosis, if one uses the segregator and gets tuberculous urine, for instance, from one side, and clear urine from the other side, he is still unable to say just

where the tuberculous urine comes from—whether it comes from the bladder on that side or the ureter on that side, or the kidney pelvis on that side; whereas, if he catheterizes both ureters and gets tuberculous urine from one side, he knows that it does not come from the bladder on that side. If he runs the catheter up to the kidney pelvis he knows that it does not come from the ureter, but does come from the kidney pelvis, or kidney itself on that side. So that the segregation method is a very inferior method, in my estimation, as compared with ureter-catheterism. Of course, one can not do anything in the way of treatment of the ureters or kidney pelvis by the use of the segregator, such as he can do by the use of ureter catheterizing methods.

One case illustrating another advantage of ureter catheterizing over segregation is that in which I put the ureter catheter about four inches into the left ureter of a male patient. At first nothing drained, but on strong aspiration with a syringe I was able to pump out a teaspoonful of pure pus that was not draining through the ureter, nor would it drain through the ureter catheter except under the influence of strong aspiration. This determined, of course, that there was no drainage of urine from that kidney—that there was an infected pus sac, which proved to be the case in our cutting down into the left lumbar region and finding a collection of more than a pint of thick pus and a stone

* Read at the meeting of the Missouri State Medical Association.

in the kidney pelvis on that side. The segregator, in this case, even if it had obtained the purulent urine from the left side and clear urine from the right side, would not have made the positive indication for operation that was made by the finding of a large collection of pus by the ureter catheter.

While the instrument illustrated does not afford the ability to catheterize both ureters at the same time, I have one which does accomplish that purpose, that is, the catheterism of both ureters at the same sitting, the drainage of both ureters coincidently, allowing of comparison as to, not only the quality of urine, but the quantity as furnished by the two kidneys at the same time and under the same general influences.

627 Century Building.

THE ROLE OF SYPHILIS AS A CAUSATIVE FACTOR IN THE PRODUCTION OF PYORRHEA ALVEOLARIS.

A. H. OHMANN-DUMESNIL, M.D.
ST. LOUIS.

Pyorrhea alveolaris, variously known as Riggs' disease, Fauchard's disease, and by some other names, remains to this day a *bête noir* to dentists. This is mainly due to the fact that they can not cure it, and the best methods at their command to-day lie in prosthetic dentistry. Without desiring to pose as a carping critic, the method is bad and is surely a *petitio in forma pauperis* to him who is able to observe and to reason.

In this trouble, as well as in others, it is necessary to determine the cause and then properly treat it or eliminate it, and it is to this very question of cause that the present is written. He who has had an opportunity to observe a number of cases of syphilis has not failed to observe that a peculiar manifestation shows itself at first in connection with the lower canine teeth. This will then spread to the incisors and at times to the first bicuspids. If the examination be pushed a little farther the gum covering the tooth root will be found to be reddened and angry-looking, and if it be pressed some pain is elicited and pus is found to exude apparently from the alveolar process. This it is which has led dentists to regard it as a purulent destruction of the alveolar, because drawing the tooth did not reveal any marked alteration of the bone during the earlier period of the disease, but rather a marked collection of pus in the alveolar cavity.

As a natural consequence it was found much easier to clean out the alveolar cavities, and patients were advised to have all the affected teeth withdrawn and replaced by a bridge, which is certainly more profitable to the dentist while more inconvenient to the patient. As an example of prosthetic dentistry it is certainly a success, but as a means of cure it is anything but such. The object of this paper, however, lies without the province of stomatology, the only object being to find and determine one of the causes of pyorrhea alveolaris. I was attracted by the name at first, and endeavored to familiarize myself with the appearance of the disease. Later on, I carefully examined every case of syphilis coming under my observation, as I do now, and I noted the facility with which pus could be made to exude from the alveoli by simple pressure on the gums. This led to a further search, which led to the discovery of the same condition in individuals who were suffering from gout and other so-called dyscrasia. The inevitable conclusion would be that these general conditions were the cause of the local symptoms observed. In other words, the trouble of the alveolar process was

nothing but a local indication of some general condition which existed and which should be corrected in addition to the elimination of the local trouble which manifested itself.

It was then that a more careful examination of the teeth of syphilitics was entered into by myself, and the result was the finding of a comparatively large number of cases of pyorrhea alveolaris. Upon request a number of dentists submitted cases to me. These were very carefully questioned, and about two-thirds gave a history of syphilis. A sufficient number existed to classify them as cases of syphilis *ignorée*, or as old cases of tertiary syphilis in which this was the only bone symptom to be observed. However this may be, the subsequent treatment showed that the etiology had been correctly established and, as a natural consequence, the treatment was successful. This, however, is not to the purpose.

In view of the fact that the few observations made by the writer have shown a greater or less interdependence between syphilis and pyorrhea alveolaris, would it not be a useful matter for every one to pay more attention to the dental trouble? To say the least, is it not a curious coincidence that Riggs' disease should be observed in so many cases of secondary syphilis as well as the late form of this period? It must also be remarked that pyorrhea alveolaris occurs as a parasymphilitic phenomenon. When we take into consideration that the teeth are observed to be all sound before syphilitic infection, and that after the disease has manifested itself it shows its presence; and, further, when systemic as well as local treatment directed to the syphilis causes both to disappear we are certainly justified in concluding that lues is a factor in the production of Riggs' disease. We are unfortunately prevented from making experimental inoculations, or the matter could be definitely settled by inoculating the pus of the pyorrhea in a subject who had never contracted syphilis. Of course, there would remain the possibility of producing nothing but a purulent infection and not a chancre.

The object of the present paper has been to call the attention of syphilologists to the point announced in the title, and observation will, beyond all doubt, lead to a number of valuable ideas and the elaboration of methods, not only for the treatment, but for the prevention as well of this most distressing disease of the teeth. It is for conservatism that we are ever striving, not for radical destruction, and there is no doubt whatever that a little care and study will enable us to save many valuable teeth which are being daily sacrificed on account of a confessed inability to successfully treat the condition known as pyorrhea alveolaris. I am sure no one will more highly appreciate a successful method than dentists, no matter how anxious they may be to construct bridges for their patients.

New Instruments.

AN IMPROVED ASEPTIC ETHERIZING INHALER.

C. FONTAINE MAURY LEIDY, M.D.
PHILADELPHIA.

This cone consists of two parts: The metallic cone, with a depression in the rim of the larger end, or base, to fit snugly over the bridge of the nose (Fig. 1, A) and a brass pretzel-shaped clamp (B) which holds the napkin or towel in position. Both parts are indestructible and can not be injured in any way by heat. The cone has two parallel indentations on either side, which hold the clamp in position as it springs into place.

Place the center of a square piece of gauze, napkin or towel over the end of the cone, allowing the loose ends to completely cover the outside surface. These ends are then tucked snugly up into the larger opening, as the fingers point in Fig.

Figure 1

1. This is done with the entire free ends, the external surface of the cone now being completely covered by the napkin or towel. The brass pretzel-shaped clamp is then inserted and pressed up toward the smaller end of the cone, until it springs

Figure 2

into place, and is clamped there by the indentations, which protrude inward as shown in Fig. 2, by the pointing fingers. This inhaler is now ready for use, exactly as seen in Fig. 2.

If the napkin or towel retains this position without support, the pretzel-shaped clamp may be entirely dispensed with. This is often the case with a heavy towel. Ether or chloroform may be used and poured into the larger opening, which fits over the face, or poured over the smaller end externally, which is covered by the one thickness, the center of the towel. Care must be taken not to force the towel too tightly into the cone, as this would prevent the entrance of air, which is regulated by placing the palm of the hand over the smaller end while the cone is over the patient's face or by placing a folded towel over this end when etherizing the patient. The cone is $3\frac{1}{2}$ inches high, base $4\frac{1}{2}$ inches by 3. The smaller end is 3 inches

by $2\frac{1}{2}$. The edges are wired with a small wire, for comfort and safety. The size is immaterial, but this size I find most useful for general work. The towel is changed within a minute's notice, should the discharges from the patient make it unfit for use. The cone can be purchased for less than one dollar, which is more reasonable than any other inhaler in the market. These points, with its durability, make it the simplest and most useful etherizing cone, especially in the clinic where many cases are anesthetized every day.

900 Pine Street.

URETHRAL DILATOR AND IRRIGATOR.

WALTER E. M. RANCHOUS, M.D.

COLUMBUS, OHIO.

The instrument is composed of two blades (*a* and *b*), a spring and a set screw. The blade, *a*, is a hollow cylinder with perforations at the distal end extending two inches back. This blade when detached at *c*, can be attached to a percolator at *d*, and used for irrigating purposes. The blade *b*, or hood, is of horseshoe shape, fitting neatly over the cylindrical blade, *a*, and when attached at *c* acts as a divulsor, scissors fashion. The spring and set screw serve to hold the blades together at all times, thus making the instrument easy for introduction.

When designing the instrument, the most important use of it, in mind, was for posterior urethral dilatation and irrigation, in gonorrheal infection of the mucous membrane of that portion of the urethra. With the anatomic structure of the urethra in mind, you will see at a glance that since the prostatic portion of the urethra is of horseshoe shape, and also the widest and most dilatable part of the canal, and since the germs form colonies along the verumontanum, in the prostatic sinuses where the orifices of the prostatic ducts make their exit into the urethra, this instrument can very readily be used to dilate the canal and compress the tissues from behind forward, thus extracting the pus and germs from these ducts. At the same time a thorough irrigation can be had by causing the fluid to flow round the mouths of the ejaculatory ducts and the pectus sinus. In the constricted or membranous portion of the canal, it is also of great use in dilating and irrigating, by making pressure over Cowper's glands and along the tract of their ducts, thus enabling you to thoroughly medicate around their orifices.

I have used the instrument successfully in the above-named conditions, and in offering it to the physician I feel that if given a trial it will aid him in treating his cases of posterior urethral gonorrheal infection that cause him so much anxiety.

1273 North High Street.

Chlorosis, Marriage and Orchitic Extract.—Dr. W. Dufougeré says that chlorosis is due to a self-intoxication of menstrual origin, and to accumulation in the blood of toxic principles which are not destroyed by the internal secretion of the ovary. By re-establishing this internal secretion chlorosis is caused to disappear. Marriage influences this secretion and restores it if it has ceased. This re-establishment of the secretion is due to the absorption during coitus of a certain specific principle which acts directly on the ovary, and stimulates it out of its torpor. Chlorosis, therefore, so far from being an impediment to marriage, is quite the reverse. The ingestion of "orchitic liquid" by chlorotics will also establish this internal secretion. Its therapeutic action is explained by its physiologic character, and agrees perfectly with the effect of "marriage" on chlorosis.—Abstract from *Gazette méd. de Nantes*.

SATURDAY, NOVEMBER 8, 1902.

THE NATURE OF TYPHOID FEVER.

The recent successful bacteriologic studies of the blood in typhoid fever have given us such results that some of the older conceptions of the nature of this disease must be remodeled. It appears from these investigations, of which there is now at hand a goodly number from various places, that bacilli may be cultivated from the blood in more than 80 per cent. of the cases and that the earlier in the disease the examination is made the greater the frequency of bacilli in the blood.

This perhaps at first somewhat unexpected turn of events is largely due to modifications in the technic employed. In the earlier part of the bacteriologic study of typhoid fever only small quantities of blood were used, and generally the inoculations were made directly on solid media or in small quantities of broth. Such small quantities of blood—at most a few drops—might not happen to contain viable bacilli, and in the next place it has been thought that the blood was not sufficiently diluted to interfere with or suspend the bactericidal action that it has on typhoid bacilli *in vitro*. In all the more recent work of this kind larger quantities of blood are taken directly from some vein, usually at the elbow, and mixed with large quantities of media. Liquid media have been employed by most of the workers, but others, like Schottmüller,¹ who has done a great deal of work in this line and examined in this way between one and two hundred cases, mix the blood directly with melted agar at a temperature of 45 C., which is then poured into plates. Schottmüller believes this method advantageous because it gives a clearer idea of the number of bacteria present and permits of a more ready recognition of contaminations. At the same time it would seem that the slowness with which the colonies spring up in many cases might be a disadvantage. He finds further that a dilution of the blood in the proportion of one to three is sufficient to yield colonies of bacilli when present. The puncture of veins for the purpose of withdrawing blood is not a very painful procedure and on the whole free from risk when done under usual aseptic conditions. Schottmüller has cultivated the bacilli from the blood as early as the second day of the fever, before the appearance of specific agglutinins, and on several occasions within the first twenty-four hours of relapses after two to three weeks of normal temperature. During the acme of the disease bacilli are numerous in the blood, but when the fever subsides

bacilli are no longer demonstrable. It seems, also, that at least many of the ephemeral rises of temperature in the course of convalescence from typhoid fever are associated with a short reappearance of bacilli in the blood. Schottmüller has found further, that the number of colonies developing on the plates of blood mixed with agar stand in a certain relation to the height of the fever and the severity of the cases, so that in addition to its evident diagnostic value the method also has prognostic significance.

Now the early and practically constant presence of typhoid bacilli in the blood in typhoid fever, and the evident relationship between the number of bacilli present and the severity of the symptoms indicate that the whole disease is dominated, so to speak, by this bacteremia. Formerly it was taught, and this teaching is still largely current, that in typhoid fever the essential point was the localization of the bacilli in the lymphatic apparatus of the intestines, and multiplying there they eventually made their way into the blood in relatively small numbers, more stress being laid on the absorption of toxins. But the occurrence of typhoid fever without intestinal lesions has shown already that these lesions are in reality not essential; furthermore, their extent and distribution are not proportionate to the severity of the disease; and now the results of bacteriologic studies of the blood seem to make it clear that in typhoid fever bacteremia plays a most prominent rôle. Schottmüller suggests that the bacilli, as a rule, enter by way of the intestines, with or without evident lesions, and that the incubation period corresponds to the time required for the bacilli to pass from the intestines through the mesenteric glands into the blood. He also believes that many of the intestinal lymphatic lesions are the result, not of primary invasion from the intestinal tract, but of hematogenous invasion, and in favor of this he urges the sudden and uniform relighting in many places of the process of the case of relapses. Be this as it may, the conception of typhoid fever as a bacteremia surely will lead to less importance being given to the intestinal treatment of typhoid fever than in the past.

Finally, mention should be made of the fact that since the introduction of bacteriologic examination of typhoid blood, it has been made clear that in the past typhoid fever has been made to stand for various related yet distinct infections caused by the so-called paratyphoid organisms. On the whole, it seems that the well-trodden field of typhoid fever still contains unexplored regions that will yield rich treasures to the clinician working with modern laboratory methods.

ETIOLOGY AND PROPHYLAXIS OF COLDS.

The word cold is probably the most used and the least understood word in modern medical practice. At this season of the year there is scarcely an ailment into whose etiology the taking of cold is not supposed to enter. Rheumatism, rhinitis, acute nephritis, tonsil-

¹ Münch. med. Wochenschr., 1902, xlix, 1562-1565

litis, catarrhal choledochitis, pneumonia, gastritis, pharyngitis, pleurisy and occasionally even metritis and oophoritis are attributed to cold. It is evident that there is concealed behind the expression a multiplicity of pathogenetic processes. As in all cases where a word is employed with a very wide meaning it is reasonably sure that its use gives a presumption of knowledge which does not really exist. Without the handy expression, "You have taken cold," which may mean nearly everything and therefore means next to nothing, to cloak ignorance of the real etiologic process at work, there would be much more careful search for the real causes of illness and a better understanding of the probable methods of prophylaxis that would lessen the number even of the minor ailments which now masquerade under the ample mantle of the word "cold."

The most familiar forms of colds are those of the respiratory passages. They are not invariably due to extreme cold, or even to considerable changes of temperature. The inhabitants of the higher, colder altitudes of Switzerland are much less subject to colds than their compatriots at lower levels. The best climate for most consumptives with tendencies to recurring catarrhal exacerbations is in the cold, rather rarefied air of somewhat elevated places. This has been the experience in this country as well as in the Alps. Our Canadian neighbors in their colder climate do not suffer as much from cold as do our own population, especially those living in crowded centers, for it is well recognized now that colds are much more frequent in our large cities than in country places. This is probably on account of the modern overheated buildings. Nansen remained for two years in the bitterly cold Arctic regions without ever suffering from a cold, and had not returned to city life for more than a week before he himself and several of his companions were confined to their rooms with catarrhal colds of the grippe type. Our own polar explorers have had similar experiences. It is not low temperature, then, that causes colds, but something intimately connected with the crowding together of many people.

There is a well-grounded impression that has been gaining vogue in recent years that the cause of colds is usually some form of microbic invasion. Already most cases of tonsillitis are frankly conceded to be of bacterial origin. Pneumonia, in the old days considered to be cold on the chest, is now referred to the pneumococcus. Rheumatism, for so long looked on as surely due to dampness and exposure, seems now to be definitely established as an acute infectious disease. There are other reasons for thinking colds due to invading bacteria. Tyndall pointed out over twenty years ago that the higher regions of Switzerland are practically free from microbes. Hence the absence of catarrhal affections in the Alps. The New York Board of Health in a recent bulletin announced that while there are many thousands of bacteria present in a cubic foot of air in the crowded tenement-house districts of the lower East

Side, there are but a few scattered micro-organisms in the same quantity of air from the wealthy, sparsely-populated residential quarter between 60th and 70th streets east of Fifth avenue. It is well recognized that inflammatory processes of mucous membranes are much more frequent among the poor than among the well-to-do, and this rarity of microbic flora in the air they breathe is at least one of the factors that accounts for the lesser incidence of colds.

It would seem, then, that the direct exciting cause of colds is not simply exposure to cold drafts, but to microbe-laden air. External cold, by disturbing circulatory conditions, especially by inducing congestion, is a predisposing cause. Head pointed out that counter irritation of certain parts of the skin produces sympathetic nervous and circulatory conditions in underlying organs. This vasomotor interference undoubtedly has its effect in preparing the soil for bacteria. Local ischemia lowers resistive vitality. The prophylaxis of colds, then, consists in the avoidance of impure air as well as the avoidance of exposure. The healthy react well and so resist invasion. The delicate have mucous membranes whose protective mechanism of reaction may be easily put out of order. For these the avoidance of crowded halls, of theaters, of large crowded stores, and, as far as possible, of crowded cars, must be the rule if they wish to escape their winter colds. It is well known now how susceptible to catarrhal complications tuberculous patients are under such exposure. Even the vigorous become susceptible, however, at times of fatigue or when through worry or emotional strain the nervous system is overborne and incapable of reaction, or when the individual is temporarily weakened by irregularities of diet or by some already existent affection. In a word, the etiology of a cold is not some mysterious disturbance of health due to weather conditions, but nearly always an acute infection, often somewhat contagious, and its prophylaxis will be best assured by a study of the conditions of lowered resistance under which infection usually takes place.

SCARLATINAL STREPTOCOCCUS SERUM IN SCARLATINA.

In the last issue¹ of THE JOURNAL occurs a full extract of Moser's recent report of his work on the treatment of severe cases of scarlet fever with a serum obtained from horses immunized with cultures of streptococci isolated from the blood of fatal cases of scarlatina. Moser assumes that the streptococci so commonly associated with scarlet fever, especially in severe and fatal cases, differ sufficiently from other streptococci to warrant the effort at manufacture of a special serum for therapeutic purposes with the special streptococci of scarlatina.

The use of ordinary streptococcus serum made by Marmorek not having any material influence on the course of severe scarlatina appeared to Moser to be an ad-

1. November 1, page 1149.

ditional reason for this attempt. Hence horses were immunized with mixtures of the cultures of streptococci obtained from fatal cases of scarlet fever, and the serum thus obtained was used in severe cases of the disease. Moser finds evidence of the efficacy of this serum in the figures that result from the comparison of the mortality rate of scarlet fever in the other hospitals in Vienna in 1901 (13.09 per cent.) with the mortality rate in his hospital since the beginning of the serum injections in 1900 (8.99 per cent.), and this in spite of the fact that the severe cases were freely admitted, the less severe cases being referred to other hospitals. Furthermore, he reports that the cases treated with the serum show early signs of improvement in the general condition and also in many of the severe local symptoms characteristic of the disease. Normal horse serum and Marmorek's new polyvalent serum did not seem to have such effects. Because only 81 of 699 patients with scarlatina were treated with this serum, the 81 cases being presumably the most severe so far as that could be determined at the time of the injections, a critical person would probably question the propriety of attributing the apparently lower death rate in this hospital to the use of the serum alone. It will also be noticed that the figures used by Moser in making his comparison do not concern comparable periods, strictly speaking.

While no one would like to doubt the reliability of the clinical observations as showing a decidedly favorable influence of the serum on the course of severe scarlatina, it is plain that much more extensive experience must be accumulated before its real value can be established definitely. But no one can find fault with Moser's effort on general grounds. Whatever the real cause of scarlatina may be, the disease is associated so constantly with streptococci, which in the majority of the severe and fatal cases are found in the blood, that it seems justifiable to believe that a really effective antistreptococcus serum would rob the disease of half its terrors. For these reasons we hope that Moser's serum will maintain the same efficacy in the hands of others as is claimed for it by its originator and that further efforts in this line may prove still more definitely successful. Streptococci offer so many obstacles to the investigator at the same time as they play so prominent a part in human infections that it may not be amiss to express the hope that much attention will continue to be given to the study of these organisms.

AN AVENUE FOR PHILANTHROPY.

The establishment of public baths is an avenue for philanthropy that is not sufficiently used. In the founding and aiding of hospitals and libraries, which are of so great need and so much appreciated, other needs of the masses should not be disregarded. At the Saratoga meeting of the Association, in an article soon to be published in *THE JOURNAL*, Dr. Ludwig Weiss quoted from Dr. Walker Laidlaw,¹ that in the eleventh and twelfth assembly districts of New York City, out of

13,657 families, 13,079 were without bathing facilities. This is a sample of conditions in the poorest sections of our large cities and illustrates the need of public baths. They are already to be found in some of the tenement districts in many of our large cities, and are made full use of and enjoyed. Buffalo, New York, Minneapolis and Chicago deserve especial praise for the public baths they have provided. Their number should be increased. It is hardly necessary to remark that equipment with shower and spray baths—not plunge or tub baths—is recommended, for hygienic reasons. As accessories there might be lectures on the hygiene of bathing by physicians selected by the medical societies, placards giving simple precautions in bathing and books on the subject. Simple gymnasia would be valuable, with instruction for underdeveloped shop girls and tradesmen of unequal development. Here we are but a step from the potent center of communal prophylaxis of disease, which is the burden of so many medical articles to-day, which in turn lack the practical bearing of suggestion of the starting point. Precepts are good; details of how to carry them out are better. Let us have more details suggested. Why is not the public bath the easiest and most natural avenue for communal prophylaxis?

THE PRINCIPLE OF LIFE.

In a recent address before the British Association for the Advancement of Science Prof. W. D. Halliburton¹ remarked that the revival of the vitalistic conception in physiologic work appeared to him a retrograde step. It is, in his opinion, a confession of ignorance and, what is still worse, a bar to progress. Why a confession of ignorance should be a bad thing is not at once apparent to every one; it has not heretofore been so considered by the greater men of science. Sir Isaac Newton is, of course, not a modern authority, but there are workers of the present day who, like him, appreciate the limitations of their acquisitions and modestly esteem themselves as only gatherers of pebbles on the shore with the great sea of knowledge still spread out before them. The vitalistic conception of the present day is simply the admission that there is something in living matter that is not identified with any known physical or chemical activities. We may find some so-called laws that it follows; that is, that it acts more or less regularly in certain definite ways, but that will not explain its essence any more than we know what gravitation is because we know how it acts. Professor Halliburton says: "It may be that there is a special force in living things that distinguishes them from the organic world. If this is so the laws that regulate this force must be discovered and measured, and I have no doubt that those laws when discovered will be found to be as immutable as the force of gravitation." He hopes, however, that it will ultimately be found amenable to known physical and chemical laws. It seems to us that the conception of vitality as a principle, force or whatever one may choose to call it, is very far from being a bar to progress. It is, on the other hand, an incentive to research as long as its mystery is undiscovered and a perpetual one if it happens to be undiscoverable. So long as it is not correlated with any physical forces, but seems to be in certain

1. N. Y. Med. Record, May 31, 1902, p. 861.

structures their controlling and guiding principle, it is certainly assuming a great deal to ask us to admit that there is no alternative, but that it must be proven identical with known physical and chemical agencies. We may do our best to prove it, but it is immodest and unscientific to be too sure that it will be proved and to base all our theories on this assumption. At present it is very far from proved.

THE DANGERS OF CLOSED STOVES.

The recent death of an eminent literary man in France from coal-gas poisoning through a defective stove has called out considerable medical comment, especially in the British medical journals. It appears that, as often happens, this accident has been followed by a number of similar ones in Great Britain and on the Continent, and they are used to point a moral—the dangers of closed stoves as compared with open grates for house heating, and self-congratulations indulged in by our insular contemporaries that the latter method of heating is the prevailing one among them. It is safe to admit that the closed stove is not the ideal warmth producer, but with a continental climate, like our own, with its extremes of cold, dependence on open grates would be still worse. It may be also that the arts of stove construction and management are more advanced in this country than in Great Britain, for accidents of sudden death from stove gas are rather rarely reported. When they do occur it is generally from carelessness or some special defect, and we believe that altogether, with nearly double the population, there are fewer deaths annually from this cause than occur in the British islands from burning due to open grates. Anthracite coal is burned in closed stoves over the whole north-western portion of the United States, and it is somewhat of a surprise to read in the *Lancet* that when thus used "it is prone to be excessively dangerous." If so, the risk is taken very lightly here, and it may be too lightly at times, for there is a danger, though generally a remote one. Many persons suffer, it is probable, in their general health from gaseous emanations without fully realizing the cause. The popular gas stoves and ranges have also their perils, as the *Lancet* points out, especially if through defect of the burners the combustion is incomplete. It is well that such facts should be known, and the death of M. Zola is a warning that we in this country may also heed, though our experience teaches us that with proper care the danger is slighter than seems to be the case abroad.

TRACHOMA IN THE UNITED STATES.

Because of the relative frequency of trachoma in the countries of the Orient and southern Europe, we have perhaps been accustomed to attach less importance than we should to the comparatively few cases in this country. Attention has been called to the danger of spreading this disease in this country by allowing immigrants who are affected with the disease to come here. Wilder¹ has pointed out that there are already large numbers of cases of trachoma in the United States, and he has especially investigated the prevalence of the disease in Illinois. In the Illinois Institute for the Blind at Jack-

sonville, 9.09 per cent. of the 451 pupils in attendance were totally blind from trachoma. As a cause of blindness trachoma was second only to blennorrhoea neonatorum, which was responsible for 17.25 per cent. of the total number of cases of blindness. At the Illinois Charitable Eye and Ear Infirmary, 5.6 per cent. of the cases treated are cases of trachoma. In the large hospitals for eye and ear diseases in the eastern part of the United States the proportion of trachoma cases is smaller, varying from 0.4 per cent. in the Massachusetts Charitable Eye and Ear Infirmary to 4.9 per cent. in the New York Eye and Ear Infirmary. In New York the larger proportion is probably explained by the numbers of poor foreigners living in the tenement districts. On the contrary, in the Illinois Eye and Ear Infirmary the cases come largely from the rural districts and are of American birth. Wilder found the disease most prevalent in the southern part of the state, and he believes that it is increasing in prevalence. The actual cause of the disease is not certainly known, but the infection is apparently usually due to either direct or indirect contact with previous cases. The vehicles of the infection in many cases are supposed to be sponges, wash cloths, basins, towels, etc. The most favorable conditions for the dissemination of the disease are furnished by intimate association of the infected persons with the healthy, together with neglect of the ordinary principles of hygiene and cleanliness. If certain precautions are taken there need never be any spread of the disease to healthy persons living about infected ones. It, like gonorrhoeal ophthalmia, is a preventable disease. The most important thing to accomplish in the prophylaxis of the disease is to impress on the patient or his parents the way in which he is dangerous to others, and to teach them how these dangers may best be counteracted. Instructions by physicians of the importance of care to prevent direct contact with the secretions from diseased eyes, and indirect contact through the medium of towels, sponges, etc., must be principally relied on to stamp out this disease in which so much can be done to prevent, but so little often to cure.

Medical News.

CALIFORNIA.

Physician Acquitted.—Dr. B. Franklin Weaver, arraigned at Bakersfield on a charge of practicing medicine without having first filed the necessary papers with the county clerk, was declared not guilty by the jury.

Personal.—Dr. William J. G. Dawson, St. Helena, has been appointed superintendent of the Home for the Feeble-Minded, Glen Ellen, and has been duly installed.—Dr. Charles E. Stone, Marysville, has been appointed superintendent of the Napa State Hospital, vice Dr. L. Franklin Dozier; Dr. Leonard M. Pulsifer, Napa, has been appointed assistant superintendent.

To Test Validity of Medical Bill.—Dr. Carl von Tiedemann, San Francisco, has applied to the Superior Court for a writ of review to test the right of Police Judge Fritz to examine into a charge of practicing medicine without a license, recently preferred against him by George G. Gere. He asserts that the statute of 1901, providing for the punishment of all persons attempting to practice medicine without a diploma satisfactory to the State Board of Medical Examiners, is unconstitutional.

Hospitals and Sanatoria.—Ground has been broken for a 160-bed hospital to be built by the Sisters of Providence in Oakland.—Dr. Joseph L. Ross, Redwood City, is building a sanatorium at Palo Alto, to cost \$15,000.—Drs. A. E.

1. Ophthalmic Record, November, 1901.

Hardin and J. E. Moutoux will open their new sanatorium at Sebastopol, January 1.—Fullerton is to have a hospital to cost \$3000.—Dr. John W. Robertson, Livermore, has purchased an additional block of ten acres and will erect a special building for the treatment of nervous and mental diseases, to cost \$30,000.—The new Berkeley Sanitarium is almost ready to receive patients.

ILLINOIS.

Chicago.

October Mortality.—The total deaths reported during October were 1964, or 120 fewer than during the preceding month, and the annual death rate was 12.70 per 1000, as compared with 12.25 in October, 1901.

Deaths of the Week.—The total deaths for the week ended November 1 were 439, or 44 less than the preceding week, but 31 more than for the corresponding week of 1901. This corresponds to an annual death rate of 12.56 per 1000. Of individuals under one year 77 died, and 79 over 60 years.

Banish Drinking Cups.—The drinking cup is to be banished from the public schools. The old-fashioned practice of drinking at the pump spout is to be substituted, provided the board of education adopts the proposition of Trustee Dr. W. A. Kuflewski, to prepare and submit to the buildings and grounds committee a plan for a drinking fountain that would provide a method of taking water without placing the lips to any vessel. Such a plan should include a constant stream of water in such quantities as to insure a sufficient amount for drinking and cleansing purposes. In speaking on his resolution Dr. Kuflewski said the cost would be little, if any, as the existing faucets could be turned to an angle of 45 degrees and adjusted to a gentle flow.

LOUISIANA.

New Orleans.

The Medical Department of Tulane University opened for its sixty-eighth annual session, October 27, with what promised to be a record-breaking attendance, and this in spite of increased entrance requirements.

Scandal in Coroner's Office.—A scandal has come to light in the coroner's office, due to a series of mysterious thefts from dead bodies in the morgue. An attaché of the office is under arrest and the coroner has requested the grand jury to probe the matter thoroughly.

Charity Hospital Changes.—On October 15, Dr. E. D. Fenner, first assistant house surgeon of the Charity Hospital, resigned his position, which he had held since February, 1898. Dr. J. M. Batchelor, second assistant house surgeon since 1896, was promoted to fill the vacancy. The vacancy existing in the second assistant house surgeons was filled at the meeting of the board of administrators, held November 3.

Anti-Leprosy Ordinance.—The following ordinance to prevent the spread of leprosy and to provide penalties for its violation, was adopted by the New Orleans City Council, October 7:

WHEREAS, The disease known as leprosy, which is contaminating and dangerous to the public health and welfare, exists in this state, and that persons afflicted with said disease are permitted to be at large, thus endangering public health.

Be It Ordained, by the Council of the City of New Orleans, That it shall be unlawful for anyone to harbor a leper or lepers, and the penalty to be imposed on anyone harboring said leper or lepers, and refusing to commit them to the care of the Leper Home, shall, on conviction before the recorder in whose jurisdiction said leper may reside, be subject to a fine of not less than five dollars, nor more than twenty-five dollars, or imprisonment for a term not exceeding thirty days.

MARYLAND.

Baltimore.

Personal.—Dr. W. Wayland Frames has been appointed visiting physician of Endowood Sanitarium for Consumptives in the suburbs, vice Dr. Walter P. Smith, deceased.

Typhoid Decreasing.—Typhoid fever is still on the decrease, there being in the last week but 3 deaths and 29 new cases reported. Pneumonia caused 11 deaths, cancer 8 and consumption 31.

The Journal of the American Medical Library Association, heretofore published in this city, will be discontinued. The proceedings of the association will hereafter be published in the *Medical Library Journal*, a quarterly devoted to medical libraries, bibliography, history and biography, the initial number of which will appear January 1.

Southern Dispensary.—The work of the Southern Dispensary has not been satisfactory to the Board of Supervisors of City Charities, which has decided to employ instead a physician and to give him an office and a female assistant, the latter to

look after the women and children. A contract will be entered into with one or more drug stores to furnish medicines. An appropriation of \$1340 was made for expenses.

MISSOURI.

St. Louis.

Proposed Sanatorium for Tuberculosis.—The movement looking to the establishment of a sanatorium for tuberculosis to be provided by the state, is well under way. It is meeting with encouragement from all directions and it is more than probable that a strongly endorsed petition will soon be presented to the legislature.

Leprosy Cured or Not.—The physician of Dong Gong, a Chinese leper who has been quarantined since November 1 last, states that by cleanliness and mild medication the leprosy has been cured. This would be gratifying but for the statement of another St. Louis specialist in skin disease, that the leprosy is not cured but is only quiescent.

About St. Louis Hospitals.—Very important additions to the hospital service in St. Louis are being made. The new City Hospital is nearing completion and will leave little to be desired in the way of building or equipment. Some effort was made to have the main buildings located to the west of the city, with an emergency hospital on the site of the old institution. The large grounds and central location of the latter induced the authorities to rebuild where the old hospital was located on Lafayette Avenue, but it is thought that the increasing demands of the city will require an additional building for convalescents near the city limits. The new Jewish Hospital, on Delmar, near the World's Fair grounds, while not large, is admirably constructed and bids fair to be well patronized. Almost adjoining this, the new St. Luke's Hospital is being built. At the old location the noise and limited space were great objections, but in the new situation, just north of Forrest Park, there will be freedom from all such drawbacks. The construction is modern in every particular and in keeping with the fine record of the hospital in which Hodgen and Mudd did their most important surgical work. The Centenary Hospital, attached to one of the medical colleges, is about ready for patients and will doubtless make a good showing. All the local colleges now have hospitals directly under the supervision of the faculty and utilized by the teaching staff. Mount St. Rose, the new hospital for tuberculosis, has just been opened for patients. It is situated on a hill at the extreme southern limits of the city. The large building will, at present rate of admission, soon be inadequate to the demand. It is under the care of the Sisters of St. Mary. So far nothing has been done with the \$1,000,000 legacy of the late Mr. Barnes for a general hospital except the selection of the grounds, but it is said that the building will soon be begun. Besides the large hospitals already in full operation, these new ones will aggregate a cost of over \$2,800,000, not including the hospital buildings for the Louisiana Purchase Exposition.

NEW JERSEY.

Personal.—Dr. Charles S. Braddock, Jr., Haddonfield, sailed for Bangkok, Siam, October 21. He will be assistant superintendent of the Royal Hospital in that city.—Dr. James T. Wrightson, Newark, has sailed to Bermuda for his health.

Mercer Hospital Wing Opened.—The keys of the new wing to Mercer Hospital, Trenton, were formally delivered to the president of the hospital by John Hall, October 31. Drs. Clark H. Gordon, E. J. Gordon, D. B. Ackley and Walter Madden have been made members of the auxiliary staff.

Hospital Staff Increased.—The work at Alexian Brothers' Hospital, Elizabeth, has so increased that it has become necessary to increase the medical staff, which now is composed as follows: Dr. John P. Reilly, president; Dr. Edward R. O'Reilly, vice-president; Dr. Joseph Funk, secretary, and Drs. Arthur Stern, Samuel Korngut, Alfred Q. Donovan, Thomas E. Dolan, George W. McCallion, Thomas F. Burnett, Elizabeth; Drs. Augustin V. Wendel and George F. Corrigan, Newark, and Dr. Walter E. Cladek, Rahway.

Typhoid Fever at Atlantic City.—Some time ago considerable publicity was given to a typhoid fever epidemic at Atlantic City, and the Academy of Medicine appointed a committee to investigate and report on the cause. The following is an abstract of the report: It was found, after careful investigation, that there was no possible source of contamination of the drinking water supply, which is derived from a series of artesian wells and from a small lake fed largely by natural springs and small streams. The sewerage system is that of West. All sewage flows through a common pumping station and thence is transported in large pipes into a government

highway of ocean water about two miles from the center of the city. During the past summer owing to a break in this pipe almost the entire sewage of the city passed directly into Penrose canal, an artificial waterway containing a comparatively small proportion of tidewater. Two authentic cases of typhoid fever can be traced to sources outside of Atlantic City, where all excreta was thrown into the sewer for four weeks and ten days respectively, with no disinfection. This contaminated the artificial waterway referred to. At another point within the city limits, known as Gardner's Basin, all the sewage of the immediate district was poured directly for many years so that at present these waters are contaminated, rendering them unsafe to use for any purpose. In these infected waters is found the strongest and most positive circumstantial evidence pointing to the source of the present trouble. The oyster supply is also considered as a potent source of contamination inasmuch as in the fattening process the oysters have been placed in water taken from the two infected waterways already referred to. With few exceptions all of the typhoid cases had indulged freely in raw oysters fattened in this way and undoubtedly contracted the disease from them. It has been ordered by the Board of Health that, in future, no oysters fattened in the infected waters be sold or delivered within the corporate limits of Atlantic City under the penalty of a heavy fine. The Atlantic City Board of Health has also issued regulations in regard to oyster fattening with a view to the proper regulation and safeguarding of the output. To the report of the committee is appended an endorsement from Dr. Alexander C. Abbott, professor of hygiene and bacteriology in the University of Pennsylvania.

NEW YORK.

Eddyites Indicted.—Mr. John Carroll Lathrop, the "healer," and Mr. and Mrs. Quimby of White Plains, have been indicted by the Westchester County grand jury on the charge of manslaughter in the second degree, and have been held in \$2,000 bail each. The case grew out of the neglect to call in a physician to Esther Quimby, who was suffering from diphtheria, and whose life, it was contended, might have been saved by proper treatment. The case has attracted considerable attention, not only because these are said to be the first indictments for manslaughter in such a case in the state, but also because public indignation was very justly aroused by the fact that while one of the Quimby children was ill at home the sister was allowed to continue in attendance at school, and the board of health was not notified until a few hours before the death.

New York City.

New York Eye and Ear Infirmary.—At the annual meeting of the board of directors of this institution it was resolved to close one of the three departments in a few weeks, owing to lack of funds.

Measles Closes Schools.—The occurrence of a serious outbreak of measles among the pupils of public school No. 13, at Rosebank, Borough of Richmond, has led the health authorities to close the school.

To Obviate Errors.—A good rule to govern ambulance surgeons has been put in force in Brooklyn. It provides that the ambulance surgeon shall bring to the hospital every person found by him unconscious, or partially so. It is hoped in this way to diminish the number of errors in diagnosis arising from confounding intoxication and injuries to the brain.

Vital Statistics.—In the statistical report just issued by the health department it is stated that the death-rate for 1901, assuming the population of the city to be 3,536,517, was 20 per 1,000, as against 20.57 in 1900. The total number of deaths was 70,720, of which 9,839, or almost one-eighth, were from tuberculosis. There were 80,735 births reported for the year.

Medical Lectures for the Laity.—A course of medical lectures for the public is one of the innovations which Columbia University is introducing this year. Beginning November 5, the lectures will be given at the College of Physicians and Surgeons in the lower lecture rooms every Wednesday afternoon at 5 o'clock until April 1, with the exception of the Christmas holidays, on anthropology, chemistry, zoology, etc.

For Poor Consumptives.—The sufferers from consumption in this city who are too poor to obtain expert treatment are to have the benefit of all that medical science can offer at a new clinic to be in the heart of some thickly populated district. The plans are under the charge of Dr. Laurence F. Flick, now head of the Free Hospital for Poor Consumptives at White Haven, Luzerne County, Pa. He has already received \$600,000

from a New York man for the purchase of suitable property, and more money is to be forthcoming for equipment and maintenance.

Trachoma in the Schools.—Mention has already been made of the prevalence of trachoma in the public schools, but it has assumed such proportions that the health commissioner has called a conference of ophthalmologists to consult as to the best way of meeting this scourge. Since the opening of the schools this fall no less than 6,667 children have been excluded from the schools because of eye affections. A published statement of the number of cases of trachoma treated in several prominent institutions this year as contrasted with the number treated in the same institutions last year gives a total of 460 for 1901 and 1,673 for the present year.

Suits for X-Ray Burns.—Dr. Samuel Lloyd, of the New York Post-Graduate School, has been sued for \$50,000 damages by a man who claims that he was severely injured by an x-ray examination made by Dr. Lloyd to determine the exact nature of a doubtful abdominal affection. Dr. Lloyd asserts that the dermatitis of which the plaintiff complains was not an x-ray burn, but was produced by the application of antiseptics before the operation. About the same time that this suit was begun a woman sued two dentists for alleged x-ray burns of the face causing destruction of her hair. Although the latter case was dismissed on a technicality, these suits indicate the responsibility incurred by users of the x-ray.

Puzzling Case of Trance.—The physicians of St. Vincent's Hospital have been both interested and puzzled over a girl who has been in the hospital for thirteen days in a state of trance. According to the history she suddenly became unconscious when about to retire one night, and was taken to the hospital the next day. She is a girl of 19, and beyond seeming to be a little moody and melancholy had apparently been in good health up to the sudden onset of the attack. Hysteria and self-hypnosis have been the diagnoses most in favor, but these views have received a set-back within the last few days by an elevation of the body temperature to between 102 and 104 F. Nourishment has been given by means of injections of predigested milk.

St. Luke's Needs \$800,000.—Appeal for an addition of \$800,000 to the general endowment fund of St. Luke's Hospital will be made to the public. In the year ending September 30, 2,663 people were treated. The expenses were \$183,059.56. Four wards are unused because of lack of funds. It was announced that the plan for building a pavilion for private patients at a cost of \$300,000 had not been abandoned. The amount received from legacies in the year was \$20,247, and for the endowment of beds \$66,346. On account of the great advances in surgery and the additional cost of the treatment of patients the figure for the endowment of beds, \$5,000 for adults and \$3,000 for children, was insufficient. It was decided to raise the price to \$7,500 for adults and \$5,000 for children.

Columbia's Report.—The report of the College of Physicians and Surgeons for the academic year 1901-2 recommends that study of the autopsy from the surgical standpoint be taken up at once. The report dwells on the fact that the rapidly increasing number of students is crowding the school beyond its limits. Six candidates for entrance had to be turned away last year, because of lack of accommodations in the laboratories. As a remedy for this, it is suggested that hereafter no conditioned students be admitted. It is expected that the attendance will be cut down next year by the new entrance rules, which will make the institution more post-graduate in character. Out of the 145 men who graduated last year, 101 secured hospital appointments, in all cases through competitive examination.

The Street Cleaning Department.—Some idea of the gigantic task that confronts the Commissioner of Street Cleaning in his efforts to keep the city in proper sanitary condition, may be obtained from a published report in which he pleads for more funds. He says that there are at present 1,301 draught horses in the department, and that each of these is required to remove daily 7,314 cubic yards, and to travel about twenty miles. The army of sweepers numbers 2,484 men, who daily sweep 908 miles of streets. Their troubles are increased by the fact that there are 14 miles of open cut for the rapid transit subway, that 1,289 buildings are in course of erection, excavations are being made for 1,562 feet of gas main, 5.43 miles of streets are undergoing repairs and 1.29 miles of water main and 22.8 miles of the city are torn up by heat, light and electric light companies.

Buffalo.

Hazing Abolished.—Hazing of freshmen and the rushes between classes have been abolished in the medical department

of the University of Buffalo. This is due to the decided action of the faculty, which apparently has been successful.

Personal.—Dr. Harvey R. Gaylord and wife have returned from Europe.—Dr. George S. Haviland will soon remove to New York City.—Dr. P. F. Hipp, East Aurora, has moved to Denver, Colo.—Dr. Mary Clayton has been appointed to the staff of the St. Lawrence Hospital, Ogdenburg.

Cost of Smallpox.—Since the disease broke out prior to the Pan-American Exposition there have been 431 cases in the city. The total expense of taking care of patients has been \$24,500. In the last epidemic in 1889 there were only 147 cases, which cost the city \$22,000. The average cost during the last epidemic was a fraction over 18 cents for each patient.

Isolation Hospital Needed.—The health commissioner urges the construction of a quarantine hospital. During the epidemic just ended the greatest number of cases treated at one time was 80, whereas the maximum capacity of the hospital was 50. Therefore, private houses had to be quarantined and hospitals made of them at great expense to the city, for the inmates in all such quarantined houses had to be provided with food, and at one time over 150 policemen were doing smallpox guard duty in one precinct. Had there been a hospital all of these cases could have been accommodated at one time and there would have been no need for the greater part of the expense. The saving to the city would have amounted to at least \$10,000.

OREGON.

Sanatorium Contract Let.—The contract for building the four-story Portland Sanatorium at Mount Tabor has been awarded, the contract price being \$17,000.

Medical Schools Open.—The medical department of the Oregon State University, Portland, opened, October 1, with an address by Dr. Simeon E. Josephi, dean of the faculty.—Willamette Medical School opened for its thirty-seventh annual session, October 1, with an enrolment of 35 students.

Graduated License Fees for Physicians.—It is announced in the lay press that physicians of Portland in the first class, doing a business of \$40,000 per year, are required to pay a license of \$15 per quarter; second class, between \$20,000 and \$40,000 per annum, \$10 per quarter; third class, between \$10,000 and \$20,000, \$10 per quarter; fourth class, between \$3000 and \$10,000, \$2.50 per quarter; fifth class, between \$2000 and \$3000, \$2 per quarter, and sixth class, under \$2000, \$1 per quarter.

PENNSYLVANIA.

Personal.—Dr. Israel Cleaver, Reading, has been appointed a member of the legislative committee of the Associated Health Authorities and Sanitarians of Pennsylvania, to represent the eleventh senatorial district in the association.

National Guard Assignments.—Orders were issued from the headquarters of the National Guard of Pennsylvania, October 25, announcing the following appointments in the medical department: Major Samuel C. Milligan, Pittsburg, surgeon Second Brigade headquarters; Major William G. Johnston, Titusville, surgeon; and First Lieutenant W. W. Robertson, assistant surgeon, Sixteenth Regiment.

Typhoid in the Twelfth.—In the Twelfth Regiment, N. G. Pa., encamped at Shenandoah, 30 or more cases of typhoid fever have occurred. Investigation by the local board of health showed that there was no typhoid among the residents; the conclusion was reached that the disease was probably brought to camp and spread by the soldiers. Although good sanitary regulations had been carried out it was decided best to move the camp. A site has been selected near by on higher ground.

Philadelphia.

New Maternity Hospital Finished.—The new maternity hospital addition to the almshouse, which was constructed at a cost of \$9,500, is fully finished and ready for occupancy. A committee has been appointed to formally accept the new building.

Proposed Medical Defense Fund.—A proposition for the establishment of a legal defense fund was introduced at the last meeting of the Philadelphia County Medical Society. It was contended that certain persons make a business of bringing damage suits against physicians and surgeons on the ground of malpractice. The proposal met with considerable opposition.

Jefferson Appointments.—At a meeting of the board of trustees of Jefferson Medical College, on October 16, the fol-

lowing appointments were made: Dr. S. Solis-Cohen, senior assistant professor of clinical medicine and physician to Jefferson Hospital, to succeed the late Dr. Wrigman; Dr. John M. Fisher, assistant professor of gynecology; Dr. Addinell Hewson, assistant professor of anatomy; and Dr. E. Quinn Thornton, assistant professor of materia medica.

TEXAS.

Physician's House Burned.—The house of Dr. George W. Allen, Flatonia, was recently destroyed by fire, with all its contents. The loss was about \$6000.

Fees in Texas.—The Texas law prescribes that traveling physicians pay \$50 occupation tax for the state and \$25 each for the city and county. Resident physicians pay no occupation tax.

Itinerant Drugless Practitioner Pays Tax.—A "Dr." Mueller, who advertised to treat by suggestion the people of New Braunfels, has had suit brought against him by the county attorney for \$50, the amount of the "occupation tax," and paid the tax.

Medical Colleges Open.—The medical department of the University of Dallas opened October 4.—The medical department of the University of Texas, Galveston, opened, October 1, with a freshman class exceeding 50 in number.—The medical department of Fort Worth University opened, October 2, with an attendance of nearly 200 students.

Providence Hospital.—This hospital, which has recently been incorporated at El Paso by a number of physicians and business men, is a general hospital chiefly intended for medical and maternity cases. The staff is as follows: Drs. Howard Thompson, Gottlieb Wehrle, Henry T. Safford, Alward H. White and Orlando C. Irwin, general medicine and obstetrics; Drs. J. Shelton Horsley, Marcus O. Wright, M. P. Schuster, Augustus L. Justice and Walter N. Vilas, surgery, and Drs. Edgar H. Irvin and Albert Wilkinson, eye, ear, nose and throat. The medical members of the board of trustees are: Dr. M. P. Schuster, president; Dr. Howard Thompson, vice-president; Dr. Alward H. White, secretary, and Dr. J. Shelton. As the hospital is largely owned and controlled by physicians, the institution will be run on a strictly ethical basis.

GENERAL.

Yellow Fever on U. S. Cruiser.—The U. S. Cruiser *Montgomery* is in quarantine at San Juan, Puerto Rico, having found one case of yellow fever on board on her way from Columbia to this country.

Medical Interne Wanted.—Examinations will be held December 9, for the position of medical interne at the Government Hospital for the Insane at Washington, D. C., the salary to be \$600. Applicants must be graduates from reputable medical colleges.

Summary of Plague at San Francisco.—During the ten months of 1902 past 35 cases of bubonic plague have been located in California, each case proving fatal. During the first six months there were 6 cases and in the last four months 29. This increase has led to alarm in other parts of the United States.

Cholera in Philippines Decreasing.—By cable October 30 it is reported from Governor Taft in the Philippines that cholera has practically disappeared from the Island of Luzon, and that in Manila there have only been an average of two cases a day during the previous ten days. In all twenty provinces are now practically free from cholera and only five provinces are now seriously affected. Chief Quarantine Officer Perry says, under date of September 19, that the disease has practically disappeared from those provinces first infected, but those most recently affected are suffering severely. He makes a conservative estimate that the cases of cholera that have actually occurred in the Philippine Islands since March 20 last aggregate 75,000, with a mortality of 75 per cent. Some towns have lost 10 per cent. of their population.

The Maltine Company's Essay Prize Award.—In the competition for the prizes of \$1,000 and \$500 for the best essays on "Preventive Medicine," offered by the Maltine Company, the first prize was awarded to Dr. W. Wayne Babcock, Philadelphia, for his essay entitled "The General Principles of Preventive Medicine," and the second prize to Dr. Lewis S. Somers, Philadelphia, for his essay entitled "The Medical Inspection of Schools—A Problem in Preventive Medicine." The judges were Drs. Daniel Lewis, New York; Charles A. L. Reed, Cincinnati, and John Edwin Rhodes, Chicago. There were 209 essays submitted from various states as follows: Pennsylvania,

25; New York, 22; Illinois, 15; Massachusetts, 12; Indiana and Ohio, 11 each; Wisconsin, 10; Iowa, 8; Michigan and Minnesota, 7 each; California, 6; Connecticut, Florida, Georgia and Missouri, 5 each; Colorado, Maine and New Jersey, 4 each; District of Columbia, Kentucky and Washington, 3 each; Kansas, Louisiana, Maryland, Montana, Nebraska, South Carolina, Texas, West Virginia and Ontario, 2 each; Alaska, Arkansas, Mississippi, New Hampshire, North Carolina, Oregon, Rhode Island, Tennessee, Vermont, Virginia and New Brunswick, 1 each; and 5 were unidentified. Thus 39 states and 2 provinces of Canada were represented. The judges say "the general high grade of their excellence has made the matter of selection very difficult."

CANADA.

The Smallpox Hospital, Ottawa, after having been closed a month has been reopened for the reception of three patients, all children of the same family.

Montreal's General Health.—Dr. Laberge, the medical health officer of Montreal, reports that the general health of that city is exceptionally good for this season of the year. There is only one very mild case of smallpox in the civic hospital; and the death rate last week was 102.

New Gymnasium for McGill University.—The building of a new gymnasium is again engaging the attention of the students and athletes of McGill University. It is proposed to raise \$100,000 for a three-story building for the accommodation of upwards of 1200 students attending the different faculties. The students themselves have already contributed a handsome little sum as a nucleus.

Instruction for Asylum Attendants in Ontario.—In order to improve the service at the insane asylums of Ontario, the Ontario government has just instituted an improved course of training for the attendants. Those entering on the course will be required to remain at the institutions until they graduate, and will be granted a diploma after two years of lectures and training. The training, as far as possible, will be similar to that received by hospital nurses.

New Professor of Hygiene at McGill University.—The medical faculty of McGill University has decided to recommend to the corporation of that institution the name of Dr. T. H. Starkey of University College Hospital, London, England, for the chair of hygiene, rendered vacant through the death of Dr. Wyatt Johnston. Dr. Starkey has had a very wide experience in hygiene in London and India, and at the present time is one of the leading hygienists of England.

Toronto Western Hospital.—The annual report of the Western Hospital of Toronto shows that the institution is in a very prosperous condition. During the past five years it has increased its work fourfold in every direction, and has made headway to the extent of \$13,000. It is the intention of the board of governors at an early date to erect a modern wing, with accommodation for 100 beds at graded prices. Nine new physicians have been appointed to the visiting staff.

The Chair of Medical Jurisprudence at Toronto University.—The medical faculty of Toronto University is having no little trouble in selecting a successor to the late Dr. Bertram Spencer to fill the chair of medical jurisprudence in that department. There are said to be no less than fifteen applicants for the position, including a number of prominent and well-known coroners of the city. At present it looks as though either Dr. John Caven, late professor of pathology, or Dr. W. H. Ellis, the professor of chemistry, will be asked to accept the chair.

Improved Sewage System for Toronto.—After dilly-dallying with the question of an improved sewerage system for Toronto for the past twelve years, the city council has at last picked up courage to submit the whole question to the rate-payers at the January municipal elections. It is proposed on the advice of the medical health officer, Dr. Charles Sheard, to ask for a vote of \$2,385,000 for this purpose; and as septic tanks and filtration on a sewage farm has been recommended by the health officer, it is altogether likely that system will be adopted. The cost of maintaining this system will be in the neighborhood of \$76,000 per annum.

Appointment of a Special Medical Immigration Officer.—In view of the large increase in immigration the Dominion government has arranged for the appointment of Dr. Leonard Ellis of St. John, N. B., as medical officer, to be attached to the immigration branch of the Department of the Interior, with special authority to examine into the health and circumstances of immigrants from the British Isles and European countries,

arriving at Canadian ports. The duties of this officer will include the examination of any immigrants rejected by the American commissioners at Canadian seaport towns. It is the intention of the government to prevent pauper immigrants landing in Canada, or those who are afflicted with dangerous diseases. Under the act passed at the last session of Parliament, the government has full authority to deport diseased immigrants and to prevent their landing in Canada.

The Smallpox Indian Trouble.—Some considerable friction has recently been caused between officials at the boundary line between Montana and the Canadian Northwest. The understanding of the matter on this side of the line is that a band of American Indians suffering from smallpox who were on a sixty days' pass from the United States Belknap Agency were turned back into Canada after having been refused admission to the Blackfoot Reservation by the agent in charge there. Although these were American Indians, the Canadian authorities provided them with medical attendance; and when they were fit to be removed, again applied to the agent for their admission into American territory, which, it is reported, was again refused as they did not belong to his agency. This explains the reports sent out from Helena, Mont., that the Canadian government was sending Canadian Indians with smallpox into the United States.

FOREIGN.

Fine for Prescribing by Mail.—A certain apothecary in Berlin has been fined about \$122 for promising a positive cure of diseases by correspondence.

Cholera Less in Egypt.—The latest reports from Egypt are that cholera has markedly lessened in its severity and prevalence. From October 25 to November 1, there were 225 cases and 212 deaths in all Egypt.

Plague Inoculation Progresses in India.—Instead of opposition to the wholesale inoculation with plague serum as a prophylaxis in India, the natives are giving their co-operation and the work is progressing satisfactorily.

Whooping Cough Serum.—The cable dispatches state that Dr. Leureaux of Brussels announces a serum for whooping cough which will greatly lessen the length and severity of the disease, as his experience thus far indicates.

Cholera rages in Jerusalem and the surrounding country. During the week ended November 1, there was 494 deaths in Jerusalem. There is great distress because of the inadequacy of medical aid and the increase in the prices of the necessities of life.

Life Insurance for Physicians in Charge of Plague Patients.—On the initiative of the mayor of Odessa the lives of six physicians who attend plague patients or make bacteriologic examinations in such cases, have been insured for a little more than \$5000 each.

Energetic Plague Quarantine at Yokohama.—Plague was discovered in Yokohama, October 6, and a vigorous quarantine was begun. A price was set on rats, and thousands were destroyed, over a thousand persons were removed across the bay to a camp, and many houses were burned. Only five new cases have occurred.

Promotion of the Scarlet Fever Serum.—The Austrian Minister of the Interior has ordered the Vienna officials, police and others, to make every effort to have all cases of scarlet fever, especially the severer ones, sent to the St. Anna Hospital for early serum treatment. The government has also made appropriations for further research in this line.

German Society for the Suppression of Venereal Diseases.—This society was formally organized at a public meeting held October 19, in the Berlin City Hall. Blaschko delivered an address on the prevalence, lesser on the dangers and Kirchner on the social importance of venereal diseases, Neisser and others on the scope and plans of the society.

Contract Practice.—The Medical Chamber of upper Austria has requested the physicians of that region to refuse to serve as attending physician for the garrison quartered at Steyr as the officer in command insists on restricting the remuneration for the work to one krone (\$0.25) a day, and makes the offer in terms that render it an insult to the profession.

Prescribing by Telephone in Finland.—This practice has assumed such proportions at Helsingfors that the authorities have had to regulate it. They require the prescription to be written down as received and telephoned back for verification, with the number. At the first opportunity the prescribing physician must sign the receipt. It is further prohibited to dispense poisons on a telephone prescription.

International Congress for Study of Professional Maladies.—The Italian government is organizing an international congress for the purpose of studying measures to prevent and cure the affections incidental to certain trades and professions. It will be held in 1904 at the time of the festivities to celebrate the opening of the Simplon, and will be supplemented by an exposition of industrial and professional hygiene.

New Pasteur Institutes in Africa.—Dr. Jameson telegraphed in September to London that rabies was terribly prevalent at the Cape, and begged to have an expert sent from the Paris Pasteur Institute to study the situation and found branch institutions. The English authorities, therefore, applied to the Paris Institute, and Dr. A. Loir from the latter has already left for Africa. He has founded branch institutions at Tunis and elsewhere and expects to have another at Boulogne soon in operation.

The New Russian Medical Review.—A new journal has been founded at Berlin for the purpose of acquainting the German reading world with what is being done in Russia. It will contain reviews of all the original articles appearing in Russian periodical literature, with a few original communications, all in German. The first number has an original work proceeding from Bobroff's clinic at Moscow on the "Operative Treatment of Exophthalmic Goiter." The editors are two well-known Russian physicians residing in Berlin, and the publisher is Max Hirsch. (*Russische Med. Rundschau*, Verlag von Max Hirsch, Berlin W. 35.)

Unique Medical Association.—Paris has recently witnessed the birth of a new association, called the "Médicale Humanitaire." It is based on the assumption that physicians will play the part of social intermediators, for which they have exceptional opportunities, knowing the needs of the sick and the discouraged poor better than any one else and, on the other hand, they are also in a condition to know the generous impulses of their wealthy patients. The association does not intend to have either regular meetings, fees or officers, but merely to direct benevolent impulses into worthy channels, and incidentally it is hoped that the new organization will acquire great influence in many questions of public and private interest.

Japanese Journal for Dermatology and Urology.—A new journal has recently been founded in Japan with this title. The original articles will appear in German, the abstracts in Japanese. The first numbers contain an article by Dohi on leprosy, which states that the nervous form is much more common there than the nodular form. He treats the latter with a mixture of ol. gynocardia and ol. oliv. ana, while he finds injections of a 1 or 2 per cent. solution of sublimate the best treatment for the nervous form, given continuously with intermissions. The statement is made in this periodical that the proportion of cases of venereal diseases in the Japanese Army fell from 70.2 per cent. to 55.5 in the last three years of the century.

Austrians Elected to German Professorships.—Dr. F. Kraus has been summoned from the medical clinic at Graz to fill Gerhardt's vacant chair of internal medicine at Berlin. This has occasioned surprise, as he is not a native German, having been born in Bohemia in 1858, and received his training under Chiari at Prague and at Vienna. He is the first Austrian to be invited to a chair in the Berlin medical faculty. His principal works have been on medico-chemical topics, and the *Allg. Med. Ct.-Ztg.* expresses amazement that His, von Noorden, Krehl and other German internists of greater renown and of about the same age, have been passed over for an outsider. Two other Austrians have recently been honored in the same way, Professor Rille of Innsbruck having been elected to the chair of dermatology at Leipzig and Professor M. Gruber of Vienna to the professorship of hygiene at Munich left vacant by von Pettenkofer. Professor Emmerich was the *extraordinarius* for the latter post, but was passed over and possibly solaced by the title and rank of regular professor conferred on him at the time.

Organization of the Profession in Austria.—Dr. A. Klein of Vienna has issued an appeal to the physicians of Austria to organize for the purpose of regulating contract practice. The present medical associations have not succeeded in remedying the evils of the present methods of sick insurance societies, the *Krankenkassen*, and consequently a national "socialist-medical congress" is summoned. He points out that the impoverishment of the members of the profession is constantly increasing, and the entire medical corps throughout Austria is profoundly moved, as they see their livelihood tottering and the future of the profession in jeopardy. Not only personal

and professional interests are at stake but also the public welfare, and silence and resignation are no longer in place, but protests, loud and emphatic, and warnings. A "socialist-medical congress" of all the physicians in the land would be a true *vox populi*, and a protest emanating from such a source would resound loud enough to penetrate to the high regions whence alone help can be derived. Such a congress would also promote local organization and closer union throughout the empire. An executive committee of ten has been appointed, which includes Stricker, Weinhardt and Schnirer, editor of the *Klin. Therap. Wochenschrift*.

LONDON LETTER.

Laws Governing Ice Cream.

As a result of the outbreak of ice cream poisoning described previously in *THE JOURNAL*, the health department of the city has issued certain regulations, which are to come into force on November 1, of which the following is a résumé: 1. Any manufacturer of or merchant or dealer in ice creams or other similar commodity who (a) permits ice creams to be manufactured or stored in any room in which there is an inlet or opening to a drain, or which is used as a living room or sleeping room; (b) in manufacture, sale, or storage omits to take any proper precaution for the due protection of such commodity from infection or contamination; or (c) omits, on the outbreak of any infectious disease among the persons employed in his business, to give notice to the medical officer of the City of London, shall be liable for every such offense to a penalty not exceeding \$10. 2. Every itinerant vendor, if not himself the manufacturer, shall exhibit in a legible manner on a conspicuous part of his barrow a notice stating the name and address of the person from whom he obtains such commodity, and if such vendor is himself the manufacturer of such commodity he shall in the same manner exhibit his own name and address, subject, otherwise, to a fine not exceeding \$10.

Benevolent Symptoms.

At the opening of the winter session at the Liverpool Medical School Sir Frederick Treves delivered a very philosophical inaugural address, in which he pointed out that many of the so-called symptoms of disease are expressions of a natural effort toward cure, and have for their end the ridding of the body of the very troubles they are supposed to represent. Inflammation is in all conditions a benevolent process, the purpose of which is cure. But for inflammation and suppuration every neglected septic prick would be fatal. Take, for example, appendicitis, with perforation. An acrid poison finds its way into the cavity of the peritoneum. The perforation is sudden, accidental, and may be preceded by no warning sign of any kind. Here, again, the disease proper may be without a single symptom. The symptoms of peritonitis which follow the perforation are distressing and urgent, but they are all benevolent in intent, and are the outcome of Nature's vigorous effort to minimize the calamity and save the patient's life. The intense pain and collapse impose on the victim absolute rest, in the most advantageous posture, that, namely, of recumbency. Peritonitis is concerned only in effecting good. It is in every instance a beneficent process. It is Nature's method of cure and is successful in millions of instances.

Bicycle Accidents: Twenty-Four Deaths in One Month.

A journal devoted to cycling has compiled a very serious list of accidents to cyclists in the short period of one month. It includes 24 deaths and 78 other serious injuries, and yet it does not profess to be complete. Examining the causes of death in this alarming list many will be found due to gross carelessness. Five deaths were due to loss of control descending hills, 3 at least to riding in traffic, one to electric tramways, 10 to collision with other vehicles or pedestrians, and the remaining 5 to other causes. In addition a policeman was killed who was run into by a cyclist.

Framboesiform Chancres.

At the Polyclinic Mr. Jonathan Hutchinson called attention to the fact that erratic chancres—i. e., extragenital ones—seldom exhibit characteristic induration. They may vary greatly in features and not infrequently they assume the condition of a mass of granulation tissue of considerable elevation not unlike a small raspberry. He showed three photographs of such chancres produced by tattooing. He also made use of this fact to support his well-known view of the identity of "yaws" or "frambesia tropica" and syphilis. This frambesiform character in the primary and secondary lesions of yaws has been insisted on by his opponents as distinguishing the latter from syphilis.

Correspondence.

A Disclaimer.

NEW YORK CITY, Oct. 29, 1902.

To the Editor:—A report has been widely disseminated through the secular press that I made a statement to some newspaper reporters that Professor William H. Welch had claimed the discovery of a universal virus or remedy which would immunize the human race from all forms of infection. No such claim was made by Professor Welch, nor has such statement been authorized by me. Yours truly,

JOHN A. WYETH, M.D.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

ASTASIA ABASIA?—LITTLE'S DISEASE?

To the Editor:—Erma Y. was born in June, 1890. For the first two hours after birth it was a question whether or not there was vitality enough to sustain life. By the use of artificial respiration, etc., reaction was finally brought about; this was immediately followed by a period of very severe convulsions, lasting about 36 hours, then in a milder form for 24 hours. All parts of the body are well developed, considering the fact that there has been no opportunity to exercise the muscles. All faculties except the power to use the voluntary muscles are normal. The intellect is clear and bright, and she understands perfectly everything spoken or read to her. If in reading a story to her one should leave out a sentence she will at once let one know the fact, and is not satisfied until the connection of the story is complete. If one is reading from a book and should lay it aside for a week or even two she will let it be known whether or not one has recommenced at the right place. She is very mindful of her little sisters, immediately seeing anything which she thinks may harm them, and warns them. The general health is perfect and she has never had any severe illness except the little troubles of childhood. The family history is perfect. She has never been able to walk or talk or control any of the voluntary muscles; she has perfect control of the rectum and bladder. She makes the sounds of a few words, such as "no," "yes," "pa," "ma," and a few other words of this character, so that they may be recognized. If placed on her feet she will sustain her own weight as long as her attention is kept away from herself, but as soon as she notices that anyone is watching what she is doing she immediately loses control of her legs and falls if not supported. In other words, she does not seem to have any control of the voluntary muscles, although if one takes hold of her hand and tells her to squeeze it she has a firm grip.

The voluntary muscles are placid. The hand shake is not spasmodic. She has had no convulsions since the one immediately following birth. The reflexes are normal. The weight is 44 pounds, the height 48 inches. The intellect seems to be perfectly normal, clear and bright; appearances and actions indicate that there is perfect comprehension of everything said or done. The strangest feature of the case to me is the fact that the intellectual powers are so strong and the motive powers so weak.

I am especially interested in this case. While it is not in my immediate family, there is a relationship existing that makes it of special interest to me. I will be glad to answer any questions or give any further information that I can. CHAS. S. HART.

ANS.—The case is one that needs a thorough examination that one might form a reliable diagnosis. From the symptoms given the most reasonable suggestion is infantile hysteria, possibly based on organic trouble, to find which would require careful study. It is barely possible that it is a case of Little's disease, although it lacks the characteristic spasmodic symptoms, and the other evidences of the organic lesions supposed to accompany this disease.—Ed.

ADVISABLE PROCEDURE WHEN PREFERRED TREATMENT IS REFUSED BY PATIENT.

Oct. 30, 1902.

To the Editor:—Dr. A. is called to see some cases of diphtheria, and after explaining the superiority of the antitoxin treatment fails to obtain consent of the family to use it and treats the cases according to older methods with success. Dr. B. is also placed in similar circumstances and fails to obtain consent to use antitoxin and refuses to treat the cases. Is Dr. A. or Dr. B. pursuing the better course?

M.

ANS.—A physician should not be obliged to compromise with his convictions. Further: If he considers antitoxin absolutely necessary, as in a laryngeal case for example, he would be wiser to give some one else the opportunity to sign a death certificate. He should not disregard humanity, however, and if he is the only physician available it would be his duty to stay and do all he can. In any event he should have his position fairly understood by the family.

DOSE FOR A CHILD.

ST. LOUIS, Nov. 3, 1902.

To the Editor:—In calculating the dose for a child, do you take the mean of the smallest and largest dose that is given to an adult and multiply that by the fraction $\frac{\text{Age}}{\text{Age} + 12}$?

J.

ANS.—Yes.

Association News.

The Committee on Medical Legislation of the American Medical Association is: Dr. H. L. E. Johnson, Washington, D. C., chairman; Dr. Wm. H. Welch, Baltimore, and Dr. W. L. Rodman, Philadelphia. The auxiliary committee of the Committee on Medical Legislation is as follows:

Alabama—
Arkansas—Dr. Frank Vinsonbaler, Little Rock; Alternate, Dr. C. Travis, Hot Springs.
Arizona—Dr. H. W. Fenner, Tucson.
California—Dr. Geo. H. Evans, San Francisco.
Colorado—Dr. Samuel D. Hopkins, Denver.
Connecticut—Dr. Max Mallhouse, New Haven.
Florida—Dr. Warren E. Anderson, Pensacola.
Georgia—Dr. Howard J. Williams, Macon.
Idaho—Dr. Robt. L. Nourse, Hailey, Idaho.
Indiana—Dr. W. N. Wishard, Indianapolis.
Indian Territory—
Illinois—Dr. Carl E. Black, Jacksonville.
Iowa—Dr. Van Buren Knott, Sioux City.
Kansas—Dr. R. A. Roberts, Kansas City.
Kentucky—Dr. J. N. McCormack, Bowling Green.
Louisiana—Dr. Chas. Chassaignac, 830 Canal St., New Orleans.
Maine—Dr. W. B. Moulton, Portland.
Maryland—Dr. John W. Chambers, Baltimore.
Massachusetts—Dr. J. F. A. Adams, Pittsfield.
Michigan—
Minnesota—Dr. Arthur Sweeney, St. Paul.
Mississippi—Dr. J. C. Hall, Anguilla.
Missouri—Dr. D. C. Gore, Marshal.
Montana—Dr. J. F. Spelman, Anaconda.
Nebraska—Dr. B. F. Crummer, Omaha.
Nevada—
New Hampshire—Dr. Chas. R. Walker, Concord.
New Jersey—Dr. Geo. E. Reading, Woodbury.
New Mexico—
New York—Dr. E. E. Harris, New York City.
North Carolina—Dr. Richard H. Lewis, Raleigh.
North Dakota—Dr. H. A. Beaudoux, Fargo.
Ohio—Dr. N. P. Dandridge, Cincinnati.
Oklahoma Territory—
Oregon—Dr. Andrew C. Smith, Portland.
Pennsylvania—Dr. John B. Roberts, Philadelphia.
Rhode Island—Dr. Gardner T. Swarts, Providence.
South Carolina—Dr. E. F. Parker, Charleston.
South Dakota—Dr. R. C. Warne, Mitchell.
Tennessee—Dr. T. J. Happel, Trenton.
Texas—Dr. J. D. Osborn, Cleburne.
Utah—Dr. E. V. Silver, Salt Lake City.
Virginia—Dr. Lewis G. Pedigo, Leatherwood.
Vermont—
Washington—Dr. J. B. Eagleson, Seattle.
West Virginia—Dr. W. P. Goff, Clarksburg.
Wisconsin—Dr. U. O. B. Wingate, Milwaukee.
Wyoming—Dr. R. Harvey Reed, Rock Springs.
U. S. Marine Hospital Service—Dr. Walter Wyman.
U. S. Navy Medical Corps—Dr. R. A. Marmion, U. S. N.
U. S. Army Medical Department—Col Chas. Smart, Asst Surgeon-General, U. S. A.

New Members.

The following is a list of new members for the month of October:

ALABAMA.
Berry, W. T., Birmingham.
Wildner, W. H., Birmingham.
Jackson, W. R., Mobile.
ARIZONA.
Chenoweth, W. F., Nogales.
ARKANSAS.
McClain, M. D., Woodson.
Bathurst, W. R., Prescott.
Walt, D. C., Altheimer.
Woolford, W. S., Kingsland.
Thibault, H., Ashvale.
Johnson, J. J., Harrison.
Ellis, L. R., Hot Springs.
CALIFORNIA.
Burrows, F. G., San Francisco.
Ewer, E. N., Oakland.
Hess, H. A., San Francisco.
Terry, W. I., San Francisco.
Crease, F. J., Bakersfield.
Peck, R. E., San Francisco.

Book Notices.

A TEXT-BOOK ON DISEASES OF INFANCY AND CHILDHOOD. For the Use of Students and Practitioners. By Henry Koplik, M.D., Attending Pediatricist to Mt. Sinai Hospital, New York. Illustrated with 169 Engravings and 30 Plates in Color and Monochrome. Cloth. Pp. 675. Price, \$5.00. New York and Philadelphia: Lea Brothers & Co. 1902.

If there is one branch of medical practice of more importance than another for the general practitioner, it is that of the diseases of children. So, while the books on pediatrics are increasing, it is by no means a bad augury, but bespeaks the fact that the profession is calling for such works and that the subject is receiving the study its importance demands. The book before us is a valuable addition to the literature. Dr. Koplik has not given us as pretentious a volume as some of the other text-books on diseases of children, but he has handled the subject in a practical and concise manner. The chapter on specific infectious diseases is especially good. Like too many authors of books on this subject, he has not given as much space to the diseases of the newborn as is desirable. This, we are sorry to say, is too commonly relegated to works on obstetrics, and in them it is nearly always inadequately treated. In discussing the treatment of the various diseases, the author is prone to be too general; full and specific information ought to be found in the text-books and nothing taken for granted. The book is well illustrated.

PHYSICAL DIAGNOSIS. Diseases of the Thoracic and Abdominal Organs. A Manual for Students and Physicians. By Egbert Lefevre, M.D., Professor of Clinical Medicine and Associate Professor of Therapeutics in the University and Bellevue Hospital Medical College. Illustrated with 74 Engravings and 12 Monochrome Plates. Cloth. Pp. 448. Price, \$2.25. Philadelphia and New York: Lea Brothers & Co. 1902.

This little work on physical diagnosis is comprehensive and includes a great deal within a small space. Each subject is

State Boards of Registration.

Utah Report.—The Board of Medical Examiners of the State of Utah met at Salt Lake City, October 6, and examined 6 candidates, of whom 1 failed.

---	----	-------------------------------------	------	--------

Minnesota Report.—The following is the report of the examination held by the Minnesota State Board of Medical Ex-

taken up systematically and the subjects are presented in a lucid manner. One is especially pleased to note the careful attention that is given to methods of examination. The description of the proper method of percussion, with the figures, is much better than is found in many of the books on physical diagnosis. Much attention is paid to the configuration of the normal and the pathologic chest, and as might be expected, a good deal is made out of the anatomic relations of the bronchi, as Lefevre's work in this respect is already well and favorably known. While, naturally, the physical diagnosis, as regards the abdomen, occupies less space than that allowed the chest, possibly a criticism might be offered in that the abdomen has received less attention than it deserves. Altogether the book is to be heartily commended.

THE TREATMENT OF TABETIC ATAXIA by Means of Systematic Exercise. An Exposition of the Principles and Practice of Compensatory Movement Treatment. By Dr. H. S. Frenkel, Medical Superintendent of the Sanatorium "Frelhof" in Helden (Switzerland). Only Authorized English Edition. Translated and Edited by L. Freyberger, M.D. (Vienna), M.R.C.P. Lond., M.R.C.S. Eng., Hon. Physician to the St. Pancras and Northern Dispensary. With 132 Illustrations. Cloth. Pp. 185. Price, \$3.00. Philadelphia: P. Blakiston's Son & Co. 1902.

Frenkel's method of treating ataxia has been before the profession for some years, but its thorough understanding will be helped by the publication of this book. It is not exactly a translation, but an adaptation to the requirements of the medical practitioner. Frenkel's treatment, as is probably well known, is based on the sensory theory of ataxia and is practically a re-education of the organs in this particular point of view. The theory is thoroughly stated in the first part of the book; the latter part is given up to the details of treatment and here the descriptions and illustrations meet the requirements very thoroughly, so that anyone who has the patience and time could conduct the treatment to a considerable extent even without elaborate apparatus. The book should prove a useful one.

THE FORCE OF MIND OR THE MENTAL FACTOR IN MEDICINE. By Alfred T. Schofield, M.D., M.R.C.S., etc., Hon. Physician to Fruedenheim Hospital. Cloth. Pp. 309. Price, \$2.00 net. Philadelphia: P. Blakiston's Son & Co. 1902.

This is a little work devoted to the subject of the psychic treatment of disease. The neglect of the mental factor in medicine, according to its author, has been a serious weakness in the past and still continues. He takes for his text throughout the "unconscious mind," which is practically what is called an automatism of the perfected organism. He maintains that the mental factor including the use of the "unconscious mind" is present in all diseases functional and organic; that it is a causal factor in most organic diseases. Of course, a discussion of the phenomena and treatment of hysteria, neurasthenia and other psycho-physical conditions have taken up a large part of the work. While in some respects the work is open to criticism, as a whole, it will be profitable to the physician who peruses it.

THE MEDICAL TREATMENT OF GALLSTONES. By J. H. Keay, M.A., M.D. Cloth. Pp. 126. Price, \$1.25. Philadelphia: P. Blakiston's Son & Co. 1902.

This is an unsuccessful attempt to make out that the medical treatment of gallstones is far superior to the surgical treatment in all except a very small number of selected cases. The author became convinced of this through his own experience. After having tried medical treatment in vain, he was about to submit to a surgical operation, when the gallstones passed and he was relieved. This, to his mind, was convincing proof of the superiority of medical to surgical treatment. About four-fifths of the book is taken up with a hasty and somewhat superficial discussion of the etiology, symptomatology and diagnosis of gallstones, and only about twenty pages are occupied with the discussion of the medical treatment. There is nothing new in his therapy.

Marriages.

ENOS E. PALMER, M.D., to Miss Florence Cook, both of Ottawa, Ill., October 22.

ADAM G. NICHOL, M.D., to Miss Bertha Check, both of Nashville, Tenn., November 5.

SAMUEL MOORE, M.D., Danville, Ill., to Miss May Smith of Philadelphia, November 5.

W. DUFF BULLARD, M.D., to Miss Anna Mary Riker, both of New York City, October 29.

GEORGE LATROBE EWALT, M.D., to Miss Emma K. Merritt, both of Baltimore, October 22.

FREDERIC C. BISHOP, M.D., to Miss Gertrude Craig, both of New Haven, Conn., October 20.

W. FRANKLIN TAYLOR, M.D., to Miss Lena Virginia Brehme, both of Laurel, Md., October 25.

JOHN M. GENTRY, M.D., Stony Fork, Pa., to Mrs. Emily J. Wilcox of Olmsville, Pa., October 15.

ALPHEUS A. SWAYZE, M.D., Hackensack, N. J., to Mrs. O. J. Shepard, at Westfield, N. J., October 6.

S. C. SCHMITT, M.D., Blue Earth City, Minn., to Miss Fannie E. Robbins of Austin, Minn., October 23.

C. DAY SHUART, M.D., Brandon, Wis., to Miss Ellen Lucy Maine of Stevens Point, Wis., October 22.

F. GREGORY CONNELL, M.D., Leadville, Colo., to Miss Isabella Stickney of Wauwatosa, Wis., October 21.

FRANCIS X. DERGIN, M.D., Chicopee, Mass., to Miss Emma Tetrault of Springfield, Mass., October 22.

ENNION G. WILLIAMS, M.D., Richmond, Va., to Miss Anna Heath Lassiter of Petersburg, Va., October 21.

CHARLES E. SNYDER, M.D., to Miss Annie E. Carville, both of Kent Island, Queen Anne County, Md., October 21.

ROY BARTLETT METZ, M.D., Cleveland, Ohio, to Miss Olive Rossiter McCleary, at Stoneboro, Pa., October 20.

FRED EVERETT WHEELER, M.D., West Paris, Maine, to Miss Annie Laura Williams of Bath, Maine, October 22.

WILLIAM CLAY ABEL, M.D., West Union, W. Va., to Miss Laura May Greene of Campello, Mass., October 22.

JOHN SHEPARD, M.D., Sheboygan Falls, Wis., to Miss Huldah Thompson of Milwaukee, at Beloit, Wis., October 22.

JOHN C. LEGRANDE, M.D., Birmingham, Ala., to Mrs. Finck of Louisville, Ky., at Chattanooga, Tenn., October 29.

HENRY ERSKINE PRESSLY, M.D., Birmingham, Ala., to Miss Mamie Moore of Marion Junction, Ala., November 5.

HARRY AUSTIN COSSITT, M.D., Morris Plains, N. J., to Miss Pauline Calvin Burns of New York City, October 22.

RICHARD MILLS PEARCE, M.D., to Miss May Harper, daughter of Dr. John H. Musser, all of Philadelphia, November 6.

PETER DUNCAN MACNAUGHTON, M.D., Calumet, Mich., to Miss Ethel Mayo Rossiter of Brooklyn, N. Y., November 5.

J. CARROLL MONMONIER, JR., M.D., Baltimore, to Miss Helen Fenwick Burr of Florida, at Washington, D. C., October 22.

CHARLES S. HOOVER, M.D., son of Dr. Collins M. Hoover, to Miss Helen Speaker Williams, both of Alliance, Ohio, October 22.

LINCOLN DAVIS, M.D., to Miss Katherine B. Crowninshield, both of Boston, Mass., at Peaches Point, Marblehead, October 21.

Deaths.

Woodford M. Vertrees, M.D. University of Louisville (Ky.), 1852, surgeon of the Sixth Kentucky Infantry, C. S. Army, a member of the Tennessee Medical Association, one of the founders of the medical department of the University of Tennessee and for quarter of a century professor of materia medica in that institution, died at his home in East Nashville, Tenn., October 22, from nervous exhaustion, after an illness of four days, aged 76. Resolutions of respect were adopted by the faculty of the medical department of the University of Tennessee and by the physicians of Nashville.

William B. Whitehead, M.D. University of Pennsylvania, Philadelphia, 1853, died in Denver, October 13, aged 70. He was a veteran of the Crimean war, through which he served as surgeon in the Russian Army, receiving the decoration of St. Stanislaus from the Czar on account of distinguished service. He also served as division surgeon in the Confederate service during the Civil war. He was one of the founders of the medical departments in the Universities of Colorado and Denver. He has been a resident of Colorado for thirty years and was instrumental in securing a sewage system for Denver.

Daniel E. Hughes, M.D. Jefferson Medical College, Philadelphia, 1875, chief resident physician at the Philadelphia

Hospital and Almshouse for twelve years, and a member of the American Medical Association, died at the hospital, October 28, from tubercular peritonitis, alleged to have been contracted as a result of partaking of food prepared by a tubercular patient at the hospital who had been pressed into service as a cook.

Joseph Sheppard, M.D. Bellevue Hospital Medical College, New York, 1849, a member of the American Medical Association, the Medical Society of New Jersey, and the Cumberland Medical Society, a surgeon in the Army during the Civil war and the oldest practitioner of Bridgeton, N. J., died at his home in that city, October 23, aged 74.

Andrew J. Baxter, M.D. Medical College of Ohio, Cincinnati, 1861, for more than twenty-five years surgeon to Alexian Brothers' Hospital, Chicago, and for a long time surgeon at Cook County and Michael Reese hospitals, died at his home in Chicago, October 25, from paralysis, after an illness of eighteen months, aged 66.

Theodore F. C. Van Allen, M.D. Albany (N. Y.) Medical College, 1883, ophthalmic and aural surgeon at St. Peter's Hospital, Albany, and some-time president and treasurer of the Albany County Medical Society, died at his home in Albany, October 28, from consumption, after an illness of about one year, aged 41.

Jacob F. Hoffa, M.D. Jefferson Medical College, Philadelphia, 1876, three times a member of the Pennsylvania legislature, and president of the Montour County Medical Society, died at his home in Washingtonville, Pa., October 27, from inflammation of the bowels, after an illness of two weeks, aged 50.

Benjamin F. Holcomb, M.D. University of Wooster, Cleveland, 1865, assistant surgeon of the Thirty-sixth Ohio Volunteer Infantry in the Civil war, and for many years a practitioner of Jackson, Ohio, died at the home of his daughter in Fostoria, Ohio, October 21, from paralysis, aged 67.

Joseph C. Rutherford, M.D. Vermont Medical College, Woodstock, 1849, surgeon of the Tenth and Seventeenth Vermont Infantry, U. S. V., in the Civil war, and a practitioner in Newport, Vt., for more than 40 years, died at his home in that town, October 20, from heart disease, aged 84.

Joseph Sylvester Richmond, M.D. Vermont Medical College, Woodstock, 1853, for a term president, and for many years secretary of the Vermont State Medical Society, and a member of the Connecticut River Medical Association, died at his home in Windsor, Vt., October 22, aged 74.

John Henry Howard, M.D. Kentucky School of Medicine, Louisville, 1875, for several years resident physician at State Hospital for the Insane No. 1, Fulton, Mo., who was under treatment for cancer of the neck, died suddenly in St. Louis, October 24, aged 75.

Charles E. Jackson, M.D. Jefferson Medical College, Philadelphia, a contract surgeon, U. S. Army, recently returned from Manila, died at the home of his parents in Massillon, Ohio, October 24, from sepsis, contracted during a surgical operation, aged 40.

James C. Merrill, M.D. University of Pennsylvania, Philadelphia, 1875, major and surgeon, U. S. Army, who had been connected for several years with the Army Medical School, Washington, D. C., died at his home in that city, October 27.

Asa B. Gardner, M.D. University of Louisville, Ky., 1874, ex-president of the Texas State Medical Association, died at his home in Bellville, Texas, from Bright's disease, October 22, after an illness of eighteen months, aged 50.

William Young, M.D. University of Glasgow, Scotland, 1842, said to have been the last surviving charter member of the New York Academy of Medicine, died at his home in Cold Spring, N. Y., October 26, aged 82.

Joseph Senay, M.D. Harvard Medical School, Boston, 1893, a member of the Massachusetts Medical Society, died at his home in Salem, Mass., from consumption, October 20, after a long illness, aged 34.

Henry A. Cayley, M.D. Ecole de Medecine et de Chirurgie, Montreal, 1890, Butte, Mont., died at St. James' Hospital, Butte, October 24, twelve days after having been shot during a quarrel, aged 34.

Charles M. Strickler, M.D. Medical College of Virginia, Richmond, 1892, died at West Rockingham, Rockingham County, Va., October 28, from typhoid fever, after an illness of four weeks.

Hubert Sleeper, M.D. Dartmouth Medical College, Hanover, N. H., 1860, who retired from practice about fifteen years ago,

died at his home in Meriden, N. H., October 22, aged between 65 and 70.

Marion B. Carter, M.D. University of Pennsylvania, Philadelphia, 1859, Richmond, Va., died at the home of his sister in that city, October 28, from pneumonia, aged 66.

Robert W. Murphy, M.D. Cooper Medical College, San Francisco, 1897, committed suicide by shooting himself through the head, October 21, while despondent, aged 28.

Henry C. Matthews, M.D. University of Vermont, Burlington, 1870, Brooklyn, N. Y., died suddenly from apoplexy, October 22, at Clifton Springs, N. Y., aged 61.

William J. W. Funnell, M.D., for half a century a practitioner of Milford, Del., died at his home in that place, October 19, after a long illness, aged 78.

Luke H. F. J. Masson, M.D. Faculté de Medecine, Paris, France, 1894, for several years a practitioner of San Francisco, died recently in Paris, aged 34.

Benjamin Lee Bird, M.D. University of Maryland, 1864, died near Leeland, Prince George County, Md., October 30, after eight weeks' illness, aged 60.

Ernest G. Carleton, M.D. College of Physicians and Surgeons, New York, 1892, Morenci, Ariz., dropped dead on the street, October 20, aged 37.

Erastus B. Bills, M.D. Yale University, 1854, a resident of Durant, Iowa, for 47 years, died suddenly at his home in that place, October 16, aged 74.

J. Franklin Appell, M.D. Harvard Medical School, Boston, 1866, died after a lingering illness, October 20, at his home in Lake City, Fla.

M. J. Belden, M.D. died at his home in Maquoketa, Iowa, October 27, from paralysis, after an invalidism of three years, aged 70.

Henry H. Lynch, M.D. New York University, 1878, died at his home in Jersey City, N. J., October 13, after a lingering illness.

James W. Davis, M.D. University of Tennessee, Nashville, 1888, died from fever at his home in Fayetteville, Tenn., October 24.

James D. Wade, M.D. New York University, 1866, of Williamsburg, N. Y., died suddenly from heart disease, October 21.

Keith Fonde, M.D. Medical College of Alabama, Mobile, 1894, of Citronelle, Ala., died in Mobile, October 10, aged 34.

John N. Greene, M.D. University of Michigan, Ann Arbor, 1889, died at Leslie, Mich., October 23, aged 51.

Deaths Abroad.

Prof. Albert Sigel, director of the Olga Sanatorium at Stuttgart, aged 62.—**Dr. A. Castro**, professor of surgery, and **Dr. M. G. del Solar**, professor of hygiene, at Buenos Ayres.—**Dr. Massoni**, interne in the hospital at Philippeville, Algiers, probably senior of all the internes in the world, as he was in his ninetieth year.—**Dr. A. Schwendt**, privat docent of laryngology and otology at Basle, October 12.—**Dr. J. Bockendahl**, professor of medical jurisprudence at Kiel, October 16, in his seventy-seventh year.—**Dr. W. Schwanert**, professor of chemistry and pharmacy at Greifswald, October 17, in his seventy-fifth year.

Dr. L. Laroyenne, professor of gynecology at Lyons, died there October 15, in his seventy-second year. His principal work has been on pelvic suppurations, surgery in children and various questions in obstetrics and gynecology. His intra-peritoneal method of hysterectomy is well known. He was president of the International Congress of Gynecology at Amsterdam in 1900 and of various local organizations.

Dr. H. Eulenberg, a prominent German authority on matters of hygiene, died at Bonn in October, aged 88. He was the founder of the *Correspondenzblatt* and of the *Archiv für Psychiatrie*, and was one of the editors of the *Vierteljahrsschrift für gericht. Med.* for eighteen years.

Manuel Carmona y Valle, M.D., City of Mexico, director of the College of Medicine in that city, died at his home in the City of Mexico, October 23.

IN TAPPING the chest in fat subjects, it is well to remember that a line drawn horizontally from nipple around the chest passes over the sixth intercostal space, the sternum and the midline.

Miscellany.

Baccelli on Malaria Without Hematozoa to be Found in the Blood.—In a recent address Baccelli observed that the theory in regard to mechanical injury caused by malaria germs is untenable. Severe malarial fevers frequently occur in which it is impossible to discover the hematozoa in the blood in the first few days. In other cases they appear, but in such scanty numbers that there can be no connection between the quantity of the germs and the severity of the symptoms. The parasites may also exist in the blood in large numbers, but if they have not attained the phase of sporulation or segmentation they are not febrigenic *per se*. One can die of malarial infection without the familiar forms of the hematozoon being found in the blood. He knew a young privat docent who was working in a laboratory with several professors whose names are famous. The young man was seized with a subcontinuous fever, but as his blood was constantly free from any trace of hematozoa the hyperscientific professors attributed his illness to anything rather than to malaria and he was progressing from bad to worse until an outside friend insisted on his taking quinin and he was promptly restored to health. Golgi denied the possibility of such cases, but Baccelli succeeded in convincing him by numerous examples that patients will die of malaria, with no hematozoa in the blood, if they are not given quinin. Golgi in a recent letter confessed that the "clinic had conquered the theorist." The clinicians of to-day can not be made to believe that malaria is contracted exclusively from mosquito bites, Baccelli observes. Both he at Rome and Gerhardt at Berlin have reproduced malaria in a healthy subject by inoculating him with blood from a malarial patient, even to the special types of the malarial fever. Mosquitoes had nothing to do with these experiments. The intravenous application of quinin is now in current use in Italy. Baccelli reported in 1900 30 cases of pernicious malaria all cured by this means. Five died out of sixteen treated by subcutaneous injection of the quinin.

Medical Organization.

No Change in Qualification for Membership.

Immediately after the Saratoga meeting of the American Medical Association, the newspapers and a few medical journals contained accounts of changes made in regard to admission of members, which, judging from the letters that have been and are still being received at this office, have been believed by many. These accounts stated that hereafter homeopaths, eclectics, etc., were to be admitted, and that all opposition to sectarian system of practice was at an end. The American Medical Association neither made any changes nor were any suggestions regarding the matter brought up for consideration. The regulation regarding membership is left to the state and territorial associations as it always has been. Many of these, however, have recently modified their constitutions, admitting to membership those who have practiced sectarian medicine, provided they renounce all allegiance to sectarianism. The by-law of the Michigan State Medical Society, published last week, covering admission to membership, says: "Every reputable and legally registered physician, who is practicing, or who will agree over his own signature to practice, non-sectarian medicine only, and to sever all connection with sectarian colleges, societies and institutions, shall be entitled to membership." This slightly modifies Section 5, of Chapter XII of the Constitution for State Societies, as prepared by the Committee on Organization of the American Medical Association, which is as follows:

"Each county society shall judge of the qualification of its own members, but, as such societies are the only portals to this association and to the American Medical Association, every reputable and legally registered physician who is practicing, or who will agree to practice, non-sectarian medicine shall be

entitled to membership. Before a charter is issued to an county society, full and ample notice and opportunity shall be given to every such physician in the county to become a member."

Already a considerable number of those who had formerly practiced sectarian medicine have openly renounced allegiance to any school and have associated themselves with regular societies.

State Medical Society Lecturers—A Factor in Organization.

Any real organization of the medical profession, state must rest on the pleasure and profit it actually re the individual physician. That state will soonest have best organization which can convince every individual that is working for his interest. Too often the individual physician has been the victim of "suckers" who have extracted his blood without adequate return. If he has not suffered himself, he has observed the operation on some of his fellows, and so is disinclined to submit to a similar procedure. But in the scheme of organization, whose great apostle is Dr. J. N. McCormack of Bowling Green, Ky., an honest effort is made to inaugurate mutual helpfulness as the bond of organization.

As to the ways by which this shall be manifested, there is ground for honest difference. But once the principle be accepted, details readily follow. To suggest a new way is the object of this note. It is in brief the appointment of a corps of lecturers by the state society, who shall give one or more lectures before county societies, at such time as may be agreed on.

To the local society will thus come a fresh face, a new teacher, along other lines than is usual. To the profession of the state, outside medical colleges will come the opportunity to speak and talk with fellow physicians and the reputation of being selected by the state society for this purpose. This will utilize some of that restless energy which is likely planning a new medical college. The state society will thus indicate its interest in the local societies. The state and local society and the lecturer are benefited, and forces which otherwise were wasted or worse are utilized for the general betterments.

As the members of the college faculties are already sufficiently well known it may safely be left to the local societies to invite these when so desired.

In a brief space it is impossible to elaborate the plan, but if its value be granted details are readily arranged so that abuses would be prevented, and the largest effectiveness secured.

Thus the councilor of each district would be the person whose advice would be invaluable in knowing the proper lecturers for the several counties in his district, and all the councilors could safely be entrusted with minor details.

The nearer the lecturer was to the society he was to address the less the traveling expenses and loss of valuable time. The selection of, say two lecturers for each live county society, would make it possible to arrange from two to four lectures at some convenient season. Probably it might be more convenient to have two of these on one day. This is a minor matter, however, after the acceptance of the general principle that thus the state society could increase its solidity with its individual members.

There is nothing in the plan that forbids the securing of more distinguished than found in any district, for some of the meetings. Nor does it encroach on the activities of the individual members in writing and discussing papers. It simply proposes to broaden the old methods of securing to the individual post-graduate instruction, within his own county. It proves that the state society is putting forth additional effort for the benefit of all its members, and so stimulates them to make fitting response. It gives those able and willing to teach a chance, without starting a new college. It seeks to increase the training of those in the field, rather than augment the present overcrowding by the making of new physicians. It is the writer's belief that state organization would be materially promoted by the tactful administration of post-graduate instruction in each county society along the lines suggested.

LEARTUS CONNOR, Detroit.

Charters for County Societies.

We have received several requests for information in regard to how blank charters should be made out. We reproduce below the charters gotten up and used by the Michigan State Medical Society and the Kentucky State Medical Society.

The small type in the Kentucky charter reads:
 "That by virtue of authority vested in the House of Delegates of this Association by the Constitution and By-laws, it hereby issues a Charter to the _____ County Medical Society, of which _____ M.D. is President, and _____ M.D. is Secretary, and the Charter Members now belonging to such Society, and to their successors in perpetuity, with all of the honors and privileges pertaining thereto, so long as such Society conforms to the Constitution and By-laws of this Association."

Michigan State Medical Society.

Know All Men by these Presents:

That by virtue of authority vested in the House of Delegates of the Michigan State Medical Society, it hereby issues this Charter to the _____ County Medical Society (constituting it a branch of the State Society), giving its Charter Members and their successors in perpetuity all the honors and privileges pertaining thereto, so long as said Society conforms to the Constitution and By-Laws of the State Society.

Given Under Authority of the House of Delegates, this _____ day of _____ 19__

The small type in the Michigan charter reads:
 "That by virtue of authority vested in the House of Delegates of the Michigan State Medical Society, it hereby issues this Charter to the _____ County Medical Society (constituting it a branch of the State Society), giving its Charter Members and their successors in perpetuity all the honors and privileges pertaining thereto, so long as said Society conforms to the Constitution and By-laws of the State Society."

The Vermont State Medical Society.

The Vermont State Medical Society has increased its membership 60 per cent. during the past year, according to the secretary, Dr. Geo. H. Gorham.

Lapeer County (Mich.) Medical Society.

The physicians of Lapeer County met at Lapeer, October 15, and organized this society, to be in affiliation with the Michigan State Medical Society. Dr. Hugh D. McColl, Lapeer, was elected president; Dr. William J. Kay, Attica, vice-president; Dr. Herbert E. Randall, Lapeer, secretary, and Dr. George W. Stone, Metamora, treasurer.

Clay-Becker (Minn.) Medical Society.

At a meeting of the physicians of Clay and Becker counties, at Moorhead, October 23, this society was organized under charter by the Minnesota State Medical Society. The following officers were elected: President, Dr. Frank H. Alexander, Barnesville; vice-president, Dr. Leonard C. Weeks, Detroit, and secretary and treasurer, Dr. Leon W. Hyde, Moorhead.

Societies.

COMING MEETINGS.

Oklahoma Territory Medical Association, Guthrie, Nov. 11, 1902.
 Southern Surgical and Gynecological Association, Cincinnati, Nov. 12-14, 1902.
 Tri-State Medical Society of Mississippi, Arkansas and Tennessee, Memphis, Tenn., Nov. 11-13, 1902.
 Indian Territory Medical Association, Muskogee, Dec. 2-3, 1902.
 Western Surgical and Gynecological Association, St. Joseph, Mo., Dec. 29, 1902.

Orange Mountain (N. J.) Medical Society.—At the meeting of this society at Orange, October 25, the address of the evening was delivered by Dr. William Osler, Baltimore, on "Errors in the Diagnosis of Typhoid Fever."

Tri-State Medical Association of Mississippi, Arkansas and Tennessee.—The nineteenth annual meeting of this association will be held at Memphis, Tenn., November 11, 12 and 13, under the presidency of Dr. James B. McElroy, Stovall, Miss.

Fond-du-Lac County (Wis.) Medical Society.—This society, originally organized in 1868, was reorganized, October 22, at Fond-du-Lac, with Dr. John S. Hall, Ripon, president; Dr. J. Henry McNeel, Fond-du-Lac, vice-president, and Dr. Flora A. Read, Fond-du-Lac, secretary and treasurer.

Sanilac County (Mich.) Medical Association.—This association was organized at Carsonville, October 17, with the following officers: Dr. Harvey W. Smith, Carsonville, president; Dr. Thomas S. Kingston, Crosswell, vice-president, and Dr. George S. Tweedie, Sanilac Center, secretary and treasurer.

Northwestern Iowa Medical Association.—This association met in annual session at Carroll, October 16, and elected Dr. James E. Conn, Ida Grove, president; Dr. William J. Findley, Sac City, vice-president; Dr. Daniel W. Wheelwright, Odebolt, secretary, and Dr. Daniel J. Townsend, Lohrville, treasurer.

Fulton County (Ill.) Medical Society.—At the annual meeting held in Canton, October 7, Dr. William F. Roberts, Norris, was elected president; Dr. Paul S. Scholes, Canton, first vice-president; Dr. William Plummer, Farmington, second vice-president, and Dr. Frank M. Harrison, Bryant, treasurer. Dr. David S. Ray, Jr., Cuba, was re-elected secretary.

San Angelo District (Texas) Medical Society.—At the meeting of this society in San Angelo, October 14, Dr. Samuel L. S. Smith reviewed in his presidential address the history of medical practice in San Angelo. Dr. Fortunatus B. Magruder was elected president; Dr. L. C. G. Buchanan, secretary, and Dr. Charles T. Cooper, treasurer, all of San Angelo.

Red River Valley District and County (Minn.) Medical Association.—This association was organized by a number of Red River Valley physicians who met for this purpose at Crookston, October 24. Dr. Charles E. Dampier, Crookston, was elected president; Dr. George S. Wattam, Warren, vice-president, and Dr. Halvor Holte, Crookston, secretary and treasurer.

Iowa State Association of Railway Surgeons.—This association held its ninth annual meeting at Des Moines, October 22 and 23. Des Moines was selected as the next place of meeting and the following officers were elected: Dr. Ira K. Gardner, New Hampton, president; Dr. Benjamin Thompson, Tama, vice-president; Dr. Albert B. Deering, Boone, secretary, and Dr. William J. Williams, Adel, treasurer.

Idaho State Medical Society.—This society met at Moscow, October 9 and 10. The principal business transacted was the formation of the North Idaho Medical Society, including the five northern counties in a district organization, which it is expected will hold semi-yearly meetings. The following officers were elected: President, Dr. Charles L. Gritman, Moscow; vice-president, Dr. Isaac S. Collins, Burke, and secretary, Dr. C. D. Parsons, Moscow.

Santa Fe Railway Medical and Surgical Society.—At the annual meeting of this society in Topeka, Kan., October 11, the following officers were elected: President, Dr. William L. Smith, Streator, Ill.; vice-presidents, Drs. Daniel L. Woods, Dighton, Kan.; James H. Wroth, Albuquerque, N. M.; Emmett C. Chapman, Fort Madison, Iowa, and Dr. George W. Miel, Denver, Colo.; secretary, Dr. Pascal W. McConnell, Topeka, and treasurer, Dr. John D. Freeman, Topeka.

Big Four Railway Surgeons' Association.—The ninth annual meeting of the surgeons of this railway system was held in Columbus, October 16. The following officers were elected: Dr. Samuel L. Ensminger, Crawfordsville, Ind., presi-

dent; Drs. Cyrus W. Chidester, Delaware, Ohio; Charles F. Smith, Kankakee, Ill.; Fred R. Belknap, Niles, Mich., and Thomas W. Moorhead, Terre Haute, Ind., vice-presidents, and Dr. Thomas C. Kennedy, Shelbyville, Ind., secretary and treasurer.

Brainard District (Ill.) Medical Society.—At the regular meeting of this society, held in Lincoln, October 23, the leading question for general discussion was: "What Is to Become of the Brainard District Medical Society?" It was the unanimous opinion that the society organization should be continued. It was voted to erect a suitable stone over the grave of Dr. Katherine Miller, who served so many years as secretary of the society. The next meeting will be held in Mason City in January, 1903.

New Haven County (Conn.) Anti-Tuberculosis Association.—This association has been incorporated by Drs. Oliver T. Osborne, Henry L. Swain, Francis Bacon, Frank W. Wright and John P. C. Porter of New Haven; Dr. Carl E. Munger, Waterbury, and others, without capital stock. The object of the association is to establish and maintain in New Haven County a sanitarium for the treatment of curable cases of pulmonary tuberculosis, and to encourage and aid all efforts put forth for the suppression and prevention of the disease.

Thurber Medical Association.—This association held its annual meeting at Milford, Mass., October 16. Dr. Nathaniel C. B. Haviland, Williston, delivered the presidential address on "The Physician; What He Owes to Himself," and resolutions were adopted on the death of Dr. George King, Franklin. The following officers were elected: Dr. Charles B. Hussey, Franklin, president and orator; Dr. Emmet W. Barry, Whitinsville, vice-president; Dr. Ambrose J. Gallison, Franklin, secretary; Dr. N. W. Sanborn, Bellingham, treasurer, and Dr. Christopher D. Albro, Milford, librarian.

Park Region District and County (Minn.) Medical Society.—Nearly a score of physicians met in Fergus Falls, October 22, to organize this society. All physicians who practice non-sectarian medicine are eligible. The territory includes Wilkin, Grant, Douglas and Otter Tail counties. The object is fraternity and improvement. The following officers were elected: Dr. Thomas N. McLean, Fergus Falls, president; Dr. John Livingston, Pelican Rapids, vice-president; Dr. Eugene A. Hensel, Alexandria, secretary, and Dr. Walter E. Truax, Breckenridge, treasurer.

Franklin County (Pa.) Medical Society.—This society held its seventy-seventh annual meeting at Wolf Lake, Chambersburg, October 14. The following officers were elected: President, Dr. A. Barr Snively, Waynesboro; vice-presidents, Drs. J. Burns Amberson, Waynesboro, and Oliver P. Stoeck, Roxbury; recording secretary, Dr. John J. Coffan, Scotland; corresponding secretary, Dr. H. Clay Devilbiss, Chambersburg; treasurer, Dr. David Maclay, Chambersburg, and censor, Dr. Theo. H. Weagley, Marion. The meeting closed after a banquet in the evening, at which Dr. T. H. Weagley presided as toastmaster.

International Association of Hospital Superintendents.—This association held its fourth annual session in Philadelphia, October 14, 15 and 16. "Hospital Organization," "Hospital Construction," "Hospital Reports and Records," "Dispensary Service," and "Hospital Equipment" were among the subjects discussed. The association declared itself against the use of hospitals to pay political debts. Two papers were read on politics in hospitals, and a general discussion followed. Papers and speakers equally condemned the practice, which, they said, was not uncommon among politicians, of redeeming promises by placing henchmen in hospitals. The officers elected were: President, John Fehrenbach, superintendent of the Cincinnati Hospital, Cincinnati; vice-president, Dr. Charles O'Reilly, superintendent General Hospital, Toronto, Canada; secretary, Daniel D. Test, superintendent Pennsylvania Hospital, Philadelphia; treasurer, A. W. Shaw, superintendent Harper Hospital, Detroit. It was decided to hold the next meeting in Cincinnati, October 20, 21 and 22, 1903.

CONFERENCE OF STATE AND PROVINCIAL BOARDS OF HEALTH OF NORTH AMERICA.

Seventeenth Annual Meeting, held at New Haven, Conn., Oct. 28 and 29, 1902.

Under the Presidency of Dr. H. M. Bracken, Minneapolis.

Report of the Committee on Communicable Diseases.

Dr. B. STANTON, Cincinnati, in the absence of the chairman, presented the following list of diseases believed to be com-

municable, dangerous to the public health and such as boards of health may properly endeavor to prevent: Typhoid fever, typhus fever, smallpox, chicken-pox, measles, scarlet fever, whooping cough, diphtheria, influenza, cholera, yellow fever, bubonic plague, mumps, German measles, glanders, hydrophobia, malaria, epidemic cerebrospinal meningitis, pneumonia, puerperal fever, epidemic dysentery, erysipelas, beri-beri, ankylostomiasis, leprosy, tetanus, anthrax, actinomycosis, trichinosis, trachoma, scabies, syphilis and gonorrhea.

After considerable discussion this report was adopted. The conference also discussed and adopted a new constitution.

Production and Control of Vaccine Virus and Antitoxins.

Dr. U. O. B. WINGATE, Milwaukee, first discussed the commercial element relative to vaccine virus, antitoxin, etc. In his experience there had been considerable difficulty with the vaccine virus. Whenever an outbreak of smallpox occurred it was a serious thing to get a supply of virus to use and then find it had no effect, and those who were exposed, who might be protected by successful vaccination, were not protected because the virus was impure. He thought some measure should be taken whereby, if vaccination was urged, a sufficient amount of protection would be given to the public, so as to obtain its confidence. He quoted from Theobald Smith, who refers to the practice that exists on the Continent. Each state or state division assumes the responsibility of preparing the vaccine virus itself, and the national government appoints inspectors, provides vaccine plants, under whose supervision the virus is prepared, tested and officially stamped, the same being done with regard to antitoxin in Germany.

As we have now a national public health organization, well equipped with experts, Dr. Wingate thought it would be practicable to have agents appointed to inspect the products of vaccine virus, and perhaps the other products, or some means might be adopted by which we could say to the public that these products are safe to use, and that they are efficacious. He did not think this could be said now of these products at all times. He believed that any recommendations which might emanate from the conference would have considerable influence in establishing a system of this kind.

Massachusetts had been producing its own antitoxin for a number of years, with good results. This is certainly a step in the right direction.

Some Questions To Be Answered in Dealing with Smallpox.

Dr. C. O. PROBST, Columbus, Ohio, stated that in Ohio since the present epidemic began, 14,224 cases of smallpox had been reported, with 376 deaths. This was probably considerably short of the actual number of cases, for many had doubtless occurred that were never recognized or reported as smallpox.

The main difficulty at present is from the people, especially the merchants, who are unwilling to accept the diagnosis of smallpox made by the local physicians. The Ohio State Board of Health appointed ten experienced physicians as medical inspectors, paying them \$10 a day and expenses. When the diagnosis of smallpox was made locally, the board insisted that the local authorities should accept it, and if called on to send someone to verify the diagnosis, the local authorities were made to pay the expense. Should the state or community pay this expense? The community usually receives the greater part of the benefit. A prompt diagnosis may prevent an epidemic. If the disease is not recognized as smallpox, or not treated as such, it is carried to other, perhaps distant, communities. Dr. Probst suggested a basis of division to be made between state and local responsibility in these cases.

Dr. Probst thought the State Board of Health should have authority to modify or set aside a local quarantine regulation, but it should use this power only in urgent cases.

He presented a plan whereby a state board of health might possibly give reasonable assurance of purity of vaccine virus. The Ohio board contemplated putting such a plan into operation, and was holding it in abeyance, hoping to have it criticized at this meeting. Two vaccine propagators, and a third might be added, are willing to enter into this arrangement. They will furnish once a month, or as often as necessary,

samples of two or three lots of vaccine virus. The size of a lot would depend on the general demand, and might be the product of one heifer, or the mixed product of several inoculated on the same day. The lots would be numbered. A sample of each lot would be examined for the number of bacteria and presence of pus organisms. Possibly a test would be made for the tetanus bacillus. The methods of examination would be published and announced, when the sample passed muster, that lot so-and-so had been examined, produced by such-and-such propagator, and the sample had been found free from pathogenic organisms. The propagator on his side would agree that any person in Ohio ordering virus of a particular lot should receive that virus and no other, unless notified to the contrary. He would not be bound to hold this virus, to his loss, specially for the Ohio trade, but would endeavor to keep a supply of it on hand.

This plan has suggested itself to the board of Ohio because of the great opposition to vaccination, occasioned largely by the lack of public confidence in the purity of commercial vaccine. The exaggerated statements of the bad results from vaccine in Cleveland, and the report of several deaths there from tetanus credited to vaccination even by the medical profession, made it highly desirable that the people of Ohio should in some way be given assurance of the purity of virus used.

DISCUSSION.

DR. SAMUEL W. ABBOTT, Wakefield, Mass., in opening the discussion on these two papers, stated that the State Board of Health of Massachusetts had examined the products of several private producers of antitoxin in 1896, and found some of them absolutely worthless, as sold in open market. Speaking of the experience of his own state on the topic of antitoxin production, he said, 1. about 180,000 packages had been produced in the nearly eight years of production up to the present date. 2. Nearly one-quarter million dollars had been saved to the state, the principal portion of which would have gone out of the state to private producers. 3. Several thousand lives had been saved which might otherwise have been lost through inability to pay the cost of life saving. 4. No untoward accidents or injuries reported in the state from the use of antitoxin in the eight years. 5. All parties absolutely satisfied with state production, including the physicians and boards of health who used the product, and the people for whose benefit it was used, and for the saving of their lives and those of their children. No one was discontented except the few who desire a change for commercial reasons only.

DR. H. D. GEDDINGS, Washington, D. C., said that the public, in buying antitoxin, was entitled in equity and in justice to receive what it paid for as advertised on the labels. To sell a serum represented to contain 2000 antitoxin units to the cubic centimeter, and then have it found on test to contain between 1000 and 2000 was certainly delivering goods under false pretenses.

In regard to vaccine virus, if there was on the market to-day a truly antiseptic, aseptic or germ-free vaccine virus, the hygienic laboratory of public health of the Marine-Hospital Service was not able to purchase it in open market. Samples of every virus that was obtainable were submitted to tests in the hygienic laboratory, the result of these examinations showing that none were truly aseptic or antiseptic, and that none were germ-free. He thought too much reliance had been placed on the alleged antiseptic property of glycerin.

DR. PETER H. BRYCE, Toronto, Ont., believed that vaccine virus from a commercial standpoint could be produced quite as well as by a government laboratory. In England no one handles government vaccine except the public vaccinators, who have received a certificate of efficiency from some educational vaccine establishment, of which there are twenty-five throughout England and Scotland. The public vaccinator is appointed by the government. He receives all articles from the national vaccine establishment, or as much vaccine as he proposes to use in a week.

He would not encourage the establishment of a national or federal laboratory or institute, where lymphs and serums

could be manufactured, until he was perfectly sure the work of vaccination could be put into trained, certified hands, and the work done in such a systematic routine manner that there would be no question that the lymph will be used this week or next week, when it is fresh.

DR. GARDNER T. SWARTS, Providence, R. I., said that if state boards of health were large enough and could obtain a sufficient appropriation, or the state was large enough to warrant an appropriation to carry on the manufacture and production of vaccine virus and antitoxins, it was all very well. When it came to a small state, like Rhode Island or Delaware, the amount of appropriation needed would be so small that it would be impracticable for the state to control an institution of this kind. If these products could be manufactured by the national government, he would have some assurance, but the question arose, as in the case at St. Louis, whether state boards or city boards, who were controlling these products, would not fall into the hands of political chimera, and the result would be that those who produced the virus were not responsible parties and the state might suffer as a consequence. There should be some control whereby these institutions could be subjected to inspection and their products.

DR. JOHN GUIERAS, Havana, Cuba, said that in Cuba there was a central station for the preparation of vaccine, which was sent all over the island, handled by state officials who were vaccinators, and during the last two years compulsory vaccination had been carried out, with the result that smallpox had not been able to gain a foothold in Cuba, although the island was surrounded by countries in which smallpox was prevalent.

Report on Vaccination.

The whole subject was referred to a committee, consisting of Drs. Wingate, Probst and Bryce, which subsequently presented the following report, which was adopted:

1. That vaccination may be defined as follows: An inoculation by scarification, puncture or injection beneath the epidermis, of a vaccine which produces, with some constitutional disturbance, the typical vaccine vesicle, which leaves, after the pock has healed, its characteristic scar.

2. That in order to obtain the most satisfactory results, vaccine must be produced either by federal, state, or provincial officials, or by private producers under the closest supervision of qualified government officials.

3. That for the greatest protection against smallpox, state and provincial laws should provide machinery whereby certified public vaccinators must be appointed for the systematic vaccination by house-to-house visitation, of all children born during any year, and at public stations or otherwise of such others as circumstances may make necessary.

4. That the evidence of successful vaccination of all school-children naturally forms a part of any system of public vaccination and certificates of such should be accepted only when signed by a municipal or local health officer.

5. That in order that the best results may be obtained, it is essential that medical colleges should be urged to provide for thorough instruction in the theory and practice of vaccination, and that all licensed physicians must hold certificates of having had practical instruction in the operation of vaccination in medical colleges, dispensaries, or public vaccine stations.

Election of Officers.

The following officers were elected for the ensuing year: President, Dr. Irving A. Watson, Concord, N. H.; vice-president, Dr. John Guiteras, Havana, Cuba; secretary, Dr. Gardner T. Swarts, Providence, R. I.; treasurer, Dr. James A. Egan, Springfield, Ill.

The time and place for holding the next annual conference were left to the executive committee.

(To be continued.)

THE NEW YORK STATE MEDICAL ASSOCIATION.

Nineteenth Annual Meeting, held in New York City, Oct. 20-23, 1902.

President, Alvin A. Hubbell, M.D., Buffalo, in the Chair.

The first session was an executive one. The important features have already appeared in THE JOURNAL, i. e., the acceptance of the report of the joint committee on conference of the two state medical organizations, the adoption of a plan of associated medical defense for the benefit of members sued for alleged malpractice, and the annual election of officers.

The Pathogenesis of Eclampsia.

DR. FREDERICK P. HAMMOND, New York City, read this paper on the second day. He reviewed the various theories advanced to explain the occurrence of eclampsia, and pointed out the necessity of judicious prophylaxis. The morning meal of the pregnant woman should consist of an abundance of fresh fruit, with weak tea, coffee or water, but no meat. Only at the midday meal should red meat be permitted. When headache, disturbance of vision, or vertigo supervene, the patient should be at once put on a diet consisting of milk with some shell-fish broths, and meat extracts should be carefully avoided. The judicious use of cathartics, with proper exercise and warm baths twice a week formed an important part of the régime of pregnancy. To avert an attack of eclampsia when imminent, he thought it was best to give chloral hydrate.

DR. WILLIAM E. SWAN, Saratoga Springs, read a paper on "Bacterial Flora of the Vaginal and Cervical Canal in Health." If a healthy vagina becomes infected by virulent organisms it will rid itself of these in from 6 to 36 hours, but if Nature's process is interfered with by the use of antiseptic douches this cleansing period may be extended to 20 hours or even three days.

Treatment in Gynecology from a Medical Standpoint.

DR. MARY GAGE-DAY, Kingston, said that in the local treatment of women prior to the menopause she found iodine, ichthyol, glycerin and boric acid specially valuable, the ichthyol being particularly well suited for those cases in which tenderness was a prominent feature. For women past the menopause the following mixture seemed better adapted: Irish moss, half an ounce; glycerin, two drams; alcohol, four ounces; boric acid, two ounces; water sufficient to make one quart. When properly made this was a bland mixture having marked healing power.

DR. J. RIDDLE GOFFE, New York City, said that the proper treatment of uterine fibroids was immediate removal by operation, whether the tumor was large or small. Most cases of fibroids complicating pregnancy result in a normal delivery at term. The electrical treatment of fibroids is not only inefficient but far from being harmless.

The Repair of Lacerations of the Pelvic Floor.

DR. JAMES HAWLEY BURTENSHAW, New York City, questioned if the majority of modern operations on the perineum really restored the pelvic floor to its normal condition. The essential point is to freshen the edges of the torn muscles and closely approximate them by sutures. Special stress was laid on the important part played by the fascia of the levator ani muscle.

Etiology of Colds.

DR. JAMES J. WALSH, New York City, opened the symposium on colds with this paper. He insisted that cold was only a predisposing factor, and that the chief element was a microbic infection. Going quickly from a heated theater to the cold air outside causes congestion of the upper air-passages and affords a good opportunity for an attack by the numerous microbes that had found lodgment while in the hot and crowded auditorium.

DR. GEORGE F. COTT, Buffalo, described the symptomatology.

The Treatment of Colds.

DR. A. ALEXANDER SMITH, New York City, said that if the person developing a cold had a body temperature of 100 F. or over, he should be kept in the house, or preferably in bed. At the outset, a moderate dose of quinin and Dover's powder is often useful, and in the early stage of a coryza the well-known "rhinitis" tablets may be used to advantage up to the point of producing a slight physiologic effect from the belladonna which they contain. In lithemic subjects the so-called alkaline treatment often acts admirably. This consists in giving one dram of bicarbonate of sodium in half a glass of water, flavored with a few drops of lemon juice, and repeating this dose in one hour. Ten grains of salicylate of sodium, repeated in one hour, and thereafter in doses of five grains every five or six hours, often produce a good result, provided the stomach bears it well. Where there is an excess of mucopurulent secretion, creosote or guaiacol carbonate should be given in small doses.

For children under twelve years of age the author preferred to treat colds by giving small doses of tincture of aconite at frequent intervals. Where there was a tendency to recurrence, cod-liver oil, small doses of quinin or the vegetable bitters were appropriate.

DR. ALFRED STENGEL, Philadelphia, read a paper on "The Newer Relation of the Pancreas to General Medicine." He said that no reliance was to be placed on fatty diarrhea as an indication of disease of the pancreas, and glycosuria was by no means a constant symptom.

The Present Position of Gallstone Surgery.

DR. WILLIAM WOTKINS SEYMOUR, Troy, read a paper which will appear in THE JOURNAL.

A Study of the Indications of Nephropexy.

DR. AUGUSTIN H. GOLLET, New York City, insisted in this paper that nephropexy was indicated whenever the kidney was sufficiently prolapsed to be entirely below the border of the last rib in front. He had done 139 nephropexies on 112 patients without a fatality.

The Relation of Obesity to Impotence.

DR. HEINRICH STERN, New York City, presented in this paper some statistics that he had gathered from personal observation bearing on this subject. They were, however, simply suggestive. The non-performance of the sexual functions might, he thought, by preventing expenditure of certain body material, facilitate the fattening process.

Unrecognized Toxic Insanities.

DR. T. D. CROTHERS, Hartford, Conn., asserted that a large percentage of the insanities occurring in the higher circles were both directly and indirectly due to the use of drugs and spirits, though often this cause was unrecognized until the later stages.

Strangulated Hernia in Children Under One Year.

DR. W. B. REED, Rome, N. Y., reported on the third day of the meeting a successful herniotomy on a male infant 27 days old. He had been unable to find on record more than eight other cases of strangulation occurring under one year of age.

DR. A. J. OCHSNER, Chicago, remarked that many of these cases were evidently not reported, for he felt that his own experience would show as many cases as the author had found recorded. Children certainly bear herniotomy very well.

Local Anesthesia in Radical Cure for Inguinal Hernia.

DR. J. A. BODINE, New York City, presented in this paper an experience with 48 cases of inguinal hernia operated on under local cocaine anesthesia. It is important to specially cocaineize the main nerve trunks. Of these three, the iliohypogastric is the easiest to recognize. The needle should be introduced in such a way just beneath the scarf epithelium of the integument as to produce edematization and acute anemia of the skin. In none of his cases was more than half a grain of cocaine used. It was interesting to note that if a cocaine solution were boiled for only a minute or two it would suffer no deterioration.

Radical Operations for the Cure of Cancer of the Stomach.

DR. WILLIAM J. MAYO, Rochester, Minn., on reviewing the literature, found that from 5 to 8 per cent. of the cases operated on radically should be expected to survive three years. Gastro-enterostomy usually prolongs life about three months, and radical operation gives an increase of fourteen months over the unoperated. If the diagnoses are made sufficiently early these statistics should be greatly improved, as the stomach is a favorable organ, having a large blood supply from several sources. He would especially warn against wasting precious time in prolonged attempts at making accurate diagnoses by tests of the stomach contents. Inflation of the stomach is an aid to diagnosis, but should be done by means of a Davidson syringe and not by swallowing the two halves of a Seidlitz powder, as the latter is a dangerous procedure. In St. Mary's Hospital during the past ten years 213 operations had been done on the stomach, 126 for non-malignant disease, with a mortality of about 5 per cent., the 92 for malignant disease yielding a mortality of 10 per cent. He had himself done 20 pylorotomies with 2 deaths.

Surgery of the Stomach for the Relief of Non-Malignant Pathologic Conditions.

DR. A. J. OCHSNER, Chicago, read this paper. He said that he had himself operated on 27 patients for non-malignant disease of the stomach. The prognosis after perforation of a gastric ulcer is always bad, even though the operation be undertaken within twelve hours; hence it is far better to treat these cases surgically before the occurrence of perforation. It has been found that serious ulceration of the stomach takes place only when there is faulty drainage, and that as the stomach dilates the shape of the organ becomes altered in such a way as to still further interfere with drainage. Proper permanent drainage is best effected by an anastomosis between the lowest point in the stomach and the duodenum, about 40 cm. from the point at which the duodenum issues through the mesentery of the transverse colon. It is ordinarily not necessary to excise the ulcer.

President's Address.

DR. ALVIN A. HUBBELL, Buffalo, took for his theme, "Reflections on Some of the Purposes and Work of the New York State Medical Association." After sketching the work of the association in general, he took up its loyalty to the Code of Ethics of the American Medical Association. This code, he said, placed no restrictions on any right action, yet it was necessary, for experience had demonstrated that it was unsafe to leave everything to an unwritten code.

Pathology and Bacteriology of Typhoid Fever.

DR. GEORGE BLUMER, Albany, pointed out that the earlier failures in attempting to isolate the typhoid bacillus from the blood arose from the fact that the technic was not such as to offset the germicidal action of the blood. These bacilli could now be demonstrated in the rose spots. As a rule they did not appear in the urine until the end of the second week, and were observed in about 29 per cent. of the cases. The typhoid bacilli had been found in the bile, usually reaching that secretion through the blood.

The Serum Reaction in Typhoid Fever.

DR. THOMAS HASTINGS, New York City, dealt with this part of the subject from a statistical point of view, and the figures which he quoted showed that positive Widal reactions, for the most part with a dilution of one in fifty, were obtained in about 95 per cent. of the cases.

Paratyphoid Fever.

DR. NATHAN E. BRILL, New York City, read this paper. He said that in his original contribution on this subject five years ago he had reported 17 cases, giving the chief clinical features of typhoid, but failing to give the Widal reaction, and had then expressed the opinion that it was a distinct disease from typhoid. Since then a good deal more had been learned about these paratyphoids. In these cases the fever usually reached its height in five days, the blood showed no leucocytosis, and the duration was a little over two weeks. The marked apathy and the extreme prostration were prominent clinical features.

DR. W. S. THAYER, Baltimore, reported five cases of arteritis and arterial thrombosis in typhoid fever.

The Modern Treatment of Typhoid Fever.

DR. W. GILMAN THOMPSON, New York City, said that our modern knowledge of the very wide distribution of the typhoid bacilli very greatly weakened the argument in favor of the administration of intestinal antiseptics. An initial dose of calomel is of benefit, but the frequent use of this drug throughout the disease is harmful and likely to cause salivation. Water should be given freely, and milk should be the chief diet, but when for any reason milk diet is not desirable, broths, egg albumin mixture and peptone preparations should be given. As soon as the temperature reaches normal or therabouts, soft-boiled eggs, junket, boiled rice and scraped beef may be successively added to the dietary. Undigested milk is as irritating as solid food. If the Brand bath treatment is employed at all, it should be in no half-hearted way, but with the chief object of stimulating the nervous system. When the temperature is 102.5 F. or over, a tub bath at 75 F. should be given for fifteen minutes, two nurses making frictions meanwhile. The speaker was positive that these tub baths were responsible

for no serious complications. When intestinal hemorrhage occurred, food should be withheld from the stomach, or some digested beef preparation given. Tincture of opium should be given by the mouth in sufficient doses to keep the patient well under its influence. Suprarenal extract was sometimes, but by no means always, of service in these cases of intestinal hemorrhage. Saline infusion would sometimes save life.

DR. ALBERT W. PRESTON, Middletown, reported an interesting case of typhoid infection, hemorrhagic typhoid pleurisy.

Advantages of Nitrous Oxid in General Surgery.

DR. H. W. CARTER, New York City, said this was the most difficult of all methods of inducing anesthesia, but the rapid and pleasant induction of narcosis, the complete recovery, the almost entire absence of vomiting or other unpleasant sequelæ and the general safety and efficiency of the method for lengthy administrations counterbalanced the expense of the method, the difficulty of its administration and the cumbersomeness of the apparatus.

A Standard Technic in Operative Surgery.

DR. EDWARD WALLACE LEE, New York City, entered a plea for greater uniformity in surgical technic to obviate the confusion which students at present experience.

DRS. A. J. OCHSNER, WILLIAM J. MAYO and J. J. WALSH, who discussed the paper, did not take kindly to the suggestions of the author, and expressed the opinion that as perfection had not yet been reached the proposed plan would hinder further progress.

Points in the Control of Emergency Hemorrhage, Both Medical and Surgical.

DR. ROBERT H. M. DAWBARN, New York City, among other points discussed, called attention in this paper to his plan of treating hemorrhage in any inaccessible part of the body by sequestering the blood in the limbs by means of a knotted towel twisted around the limb at its junction with the body. This so reduces the blood pressure as to make the patient feel faint; it is a temporary bleeding into one's own vessels, and after sufficient time has elapsed for the formation of a clot at the seat of hemorrhage, the blood is gradually allowed to return from the limbs into the general circulation. The constricting bandage should not be applied so tightly as to stop the pulse on the distal side of the bandage.

DR. F. W. HIGGINS, Cortland, said that many cases of epistaxis could be controlled by pressure with the finger on a spot situated about one-third of an inch within the anterior nares.

DR. A. J. OCHSNER mentioned as a new treatment for hemophilia the giving of four to six whites of eggs three times a day.

Pneumonia from the Bacteriologic Standpoint.

DR. A. C. ABBOTT, Philadelphia, opened the symposium with this paper. He said there was conclusive proof that the *Micrococcus lanceolatus* does produce spreading inflammatory exudates having all the characteristics of the exudate of acute pneumonia in man. There was apparently no relation between the virulence of the organism and the production of toxin.

Leucocytosis in Pneumonia.

DR. ALEXANDER LAMBERT, New York City, discussed this topic. He said that the intensity of the leucocytosis was not always in proportion to the severity of the symptoms, and that leucocytosis alone was of no value in prognosis. Mild cases usually showed a leucocytosis of 6,000 to 12,000; severe cases, 30,000 to 50,000. To be of much assistance the leucocytosis must be determined almost daily. In a study that he had made of the leucocytosis in 87 cases of acute lobar pneumonia it was found that when the leucocyte count was below 7,000, i. e., was persistently subnormal, it pointed almost invariably to a fatal termination. When resolution was delayed, the leucocytosis persisted, and when there was an extension of the pneumonic process in the same or in the other lung, the leucocytosis was increased. When empyema occurred as a complication there was apt to be a doubling of the leucocyte count.

Treatment of Pneumonia.

DR. JOSEPH W. GROSVENOR, Buffalo, concluded as follows: A mild pneumonia may easily recover without medicinal treat-

ment. Blood letting is only admissible in very robust persons having marked cyanosis and great dyspnea. Toxemia should be controlled by securing elimination of the toxins and increasing the vital resistance. Alcohol being a cardiac depressant is not useful in threatened heart failure. Serum therapy is still in an experimental stage.

The Finsen Light Treatment of Smallpox.

DR. FRANCIS P. KINNICUTT, New York, said that since 1894 the Finsen treatment of the suppurative stage of smallpox, i. e., by keeping the patient in a room from which the blue, violet and ultra-violet rays of light are excluded by the interposition of red fabric, had been given extensive trial, and with very encouraging results. The earlier the treatment was commenced the better the results, and it was essential to success that it be kept up uninterruptedly until the vesicles have all dried up.

The Roentgen Ray.

DR. EDEN V. DELPHEY, New York City, described briefly the more important pieces of apparatus in general use, and outlined the physics of the subject.

DR. CARL BECK, New York City, presented radiographs to illustrate what an important aid the Roentgen ray is in the treatment of fractures.

DR. CHARLES WARRENNE ALLEN, New York City, reported 50 consecutive cases of cancer treated by the Roentgen ray. The persons varied from 15 to 80 years; 22 were males. There were 33 cases of epithelioma of the rodent ulcer type and 10 cases of cancer of the breast, 7 of them recurrent. Only 8 per cent. were unimproved; 20 per cent. were improved, but still under treatment; 52 per cent. had been discharged as cured. The writer admitted that the α -ray might do decided injury aside from producing burns, as, for example, the production of a septicemia by the accumulation in the system of the toxins resulting from the breaking down of the tumor. The method was not to be used in all forms of cancer, and the improvement in appropriate cases is greater than could be obtained at present from any other known method.

DR. EDEN V. DELPHEY read a paper on "The Roentgen Ray in Gynecology."

DR. JOSEPH B. COOK, New York City, said that the results of α -ray examinations of the pelvis of a pregnant woman could not compare with those obtained by one skilled in obstetric palpation. It might possibly prove of value in cases of multiple pregnancy.

DR. WILLIAM JAMES MORTON, New York City, exhibited a small and comparatively inexpensive lamp which he said would do all the work of the large and complicated Finsen light. By substituting iron for carbon in the electric arc an abundance of ultra-violet rays was obtained. In the treatment of carcinoma by the α -ray he carefully avoided the use of screens, because he felt that a very wide application of this potent agent was essential to the best results.

DR. WILLIAM B. COLEY, New York City, said that after some experience in this field, he felt that the α -ray would prove chiefly useful as an aid rather than as a substitute for operation in cases of cancer. His experience had been that many of these cases recur after a short time. The application of the α -ray immediately after excision of the visible portions of a primary carcinoma seemed to him most important.

Election of Officers.

The following officers were elected for the ensuing year: President, Dr. Frederick Holme Wiggin, New York City; vice-president, Dr. William H. Thornton, Buffalo; secretary, Dr. Guy D. Lombard, New York City, and treasurer, Dr. Edward H. Squibb, Brooklyn.

OREGON STATE MEDICAL SOCIETY.

Twenty-ninth Annual Meeting, held at Portland, Ore., Sept. 10-12, 1902.

President, Dr. Charles J. Smith, Pendleton, in the Chair.
Welcome.

Mayor Williams of Portland delivered the address of welcome and spoke appreciatively of the value of the work of Oregon

physicians and of the great advances made by the medical profession during the last few years.

Outdoor Treatment of Tuberculosis.

DR. EDGAR P. HERSHEY, Denver, Colo., presented a paper on "General Treatment of Tuberculosis," in which he enlarged on the advantage of breathing the open air. There is no special climate that will cure tuberculosis. What is needed is to get out in the open air. Let the patient eat his food, and become hardened to the climate. A large number of consumptives come to Colorado for treatment. There is one kind of a climate that is good for one class of patients and another for another. The main thing is to get out into the open air.

DR. HARRY LANE, Portland, discussed "The Outdoor Treatment of Tuberculosis." He also was in favor of the patient leading a rough outdoor life. "We should be very careful when out camping, though, to have a tent that will admit the air, or it will be worse than if we were in the house." He also spoke of the value of having roof gardens where the patients could enjoy the open air and be comfortable.

DR. WOODS HUTCHINSON thought "it should be made a penal offense for physicians to give drugs in the treatment of tuberculosis. It is an established fact that the open-air treatment is the only one that is valuable."

Typhoid Fever.

DR. ALBERT E. MACKEY, Portland, in his paper "Modern Methods of Diagnosis," discussed the best methods of diagnosing typhoid fever.

DR. HOLT C. WILSON, Portland, in his discussion of "The General Treatment," did not consider cold baths and cold applications a valuable means for lowering the temperature. These statements were combated vigorously by a number of members.

Surgical Treatment of Goiter.

DR. ANDREW C. SMITH, Portland, discussed this subject and said that the death-rate had been diminished from 40 per cent. to less than 1 per cent. by the evolution of operative technic. He dwelt on the value of making transverse incisions lower in the neck for cosmetic purposes and advised the local use of general anesthesia as it eliminates all danger of injuring the voice.

Appendicitis.

A symposium on this subject was held and the usual amount of discussion indulged in. The topic was divided as follows:

"Medical Aspects," Dr. Woods Hutchinson, Portland.
"Diagnosis," Dr. Kenneth A. J. Mackenzie, Portland.
"Surgical Treatment," Dr. Andrew C. Smith, Portland.
"Surgical Technic," Dr. George F. Wilson, Portland.
"Surgical Complications," Dr. Andrew J. Giesy, Portland.
"Prognosis," Dr. Jacob A. Fulton, Astoria.

Reorganization.

The draft of the constitution and by-laws presented last year was indorsed by the executive committee. This committee's work was to formulate rules and regulations by which county and district societies may be affiliated with the state medical society on the plan suggested by the American Medical Association.

The executive committee submitted its recommendations, with the following statement of the name and objects of the association:

The purpose of this association shall be to federate and bring into one compact organization the entire medical profession of the state of Oregon, and to unite with similar associations in other states to form the American Medical Association; with a view to the extension of medical knowledge, and to the advancement of medical science; to the elevation of the standard of medical education, and to the enactment and enforcement of just medical laws; to the promotion of friendly intercourse among physicians, and to the guarding and fostering of their material interests; and to the enlightenment and direction of public opinion in regard to the great problems of state medicine; so that the profession shall become more capable and honorable within itself, and more useful to the public in the prevention and cure of disease, and in prolonging and adding comfort to life.

Component societies shall consist of those county and district medical societies which hold charters from this association.

Portland vs. Multnomah.

After a hot debate it was decided that new members would be admitted to the Portland Medical Society hereafter by a

majority vote. A committee was appointed to have charge of the admission of new members, and their vote will be considered final. The American Medical Association recognizes but one medical society in a county, and in Portland there are two. The old Portland Medical Society, now known as the Portland City and County Society, gained recognition at the last meeting. In order, then, for the members of the Multnomah Medical Society to become members of the American Medical Association it will be necessary for them to change their membership.

Election of Officers.

The election of officers resulted as follows: President, Dr. H. Waldo Coe, Portland; vice-presidents, Drs. F. N. Van Dyke, Grant's Pass, J. A. Geisendorffer, The Dalles, and James P. Tamiesie, Hillsboro; secretary, Dr. Alexander D. Mackenzie, Portland, and treasurer, Dr. Mae H. Cardwell, Portland.

Banquet.

The meeting closed with the annual banquet at the Hotel Portland.

Portland was selected as the place of meeting for 1903.

ORLEANS PARISH (LA.) MEDICAL SOCIETY.

Stated Meeting, held at New Orleans, La.

Yellow Fever and Mosquitoes.

DR. OLIVER L. POTHIER, New Orleans, who was a member of the recent United States Public Health and Marine-Hospital Commission on the Investigation of the Yellow Fever and Mosquitoes in Vera Cruz, gave a short account of his experiences. Yellow fever, he said, was endemic in Vera Cruz, and there was always plenty of material for investigation. Yellow fever that increased in the dry months, decreased in the wet period (April, May and June), began to increase in July and continued prevalent until the advent of cold weather (November and December). These facts were well explained by the theory of the mosquito in the propagation of the disease. During the dry season, mosquitoes (*Stegomyia fasciata*) were abundant, but during the wet season the nuisance abated. In July the insects began to swarm again.

The mortality of yellow fever in Vera Cruz was extremely high, due either to the virulent form of the disease, or, more likely, to lack of proper treatment in the hospitals. On admission the patient was given a dose of citrate of magnesia and an enema of permanganate of potash. After that he had practically no treatment. He was starved, but given an abundance of Vichy water. He might smoke or walk about the ward if he wished. The physicians of Vera Cruz were anxious to obtain means to prevent the disease and methods for accurate early diagnosis. They, therefore, warmly welcomed investigators. The government was willing and anxious to furnish all facilities. The patients were easily handled and submitted willingly to experiments.

Dr. Pothier preferred not to divulge any further information as to the commission's work than had already been given to the newspapers. He said, however, that the cause of yellow fever had been determined to their satisfaction. The *B. Sanerelli* was doomed. It stood in no etiologic relation to yellow fever. The work of Reed and Carroll as to the transmission of yellow fever by *Stegomyia fasciata* had been entirely corroborated. There still remained a great deal to be done, particularly in the way of confirmation and investigation and, more especially, even with regard to the question of quarantine.

The quantity of this variety of mosquito in Vera Cruz was enormous, due principally to the custom of storing drinking water in barrels all over the house. The barrels were literally alive with larvæ, some containing as many as 100 to 150 larvæ to the glassful. Malaria in Vera Cruz was prevalent in August and September and again in the spring. The hospitality and kindness of physicians had been very great; nothing had been left undone to accommodate the commission in every way.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

Gonorrheal Conjunctivitis.

Merck's Archives recommends the following silver salts in treatment of inflammatory conditions:

R. Largin 3i 4|
Aq. destil. 3vi 180|

M. and dispense in amber-colored bottle. Sig.: Bathe the eyes freely with this, lukewarm, five times daily.

Largin contains 11 per cent. of silver and is soluble in about ten parts of water. It is reported as non-irritating and not precipitated by sodium chlorid or albumin.

Ichthargin may be used in the following strength:

R. Ichthargin gr. xxx 2|
Aq. destil. 3viii 240|

M. and dispense in amber-colored bottle. Sig.: Bathe the eyes freely with this, lukewarm.

Ichthargin is a combination of silver and ichthyol, and contains about 30 per cent. of silver. It is soluble in water.

Eczema Due to Intestinal Intoxication.

Dr. Nelken, in *N. Y. Med. Jour.*, recommends the following in cases of intestinal auto-intoxication:

R. Hydrarg. chloridi mitis gr. i 106|
Salol gr. xx 130|
Guaiaecol carb. gr. xv 1|
Pulv. pepsini gr. xxx 2|

M. Ft. Chart. No. xii. Sig.: One powder to be taken three times a day. A restricted diet is recommended by the author; greasy food and sweets as well as fruits and pastry in any form should be forbidden. The following ointment is applied locally:

R. Aq. picis liq. 3i 4|
Ung. aq. rosæ 3i 30|
Ung. zinci oxidi 3ii 60|

M. Sig.: To be used locally night and morning; washing with plain water is forbidden, but twice a week water with which sufficient bran has been added to make it milky should be used, and the face kept clean with a cloth saturated with olive oil.

A Rubifacient Cataplasm.

The following is recommended by *Prov. Medical* as a local counter-irritant:

R. Barley pulverized 3iii 90|
Vinegar 3vii 28|
White of eggs No. iii.
Water, q. s.

Mix cold and make a kind of paste to be spread on cloth and dusted with seven teaspoonfuls of powdered pepper, and apply locally.

Impetigo Contagiosa.

Dr. M. F. Engman, in *Pediatrics*, recommends the following in the treatment of impetigo contagiosa:

R. Sulphuris precip.
Zinci oxidi
Potassii sulphid, aa 3i 4|

M. Sig.: Apply locally night and morning.

Bunions.

These painful enlargements, according to the *Phil. Med. Times*, are amenable to treatment by applying static sparks and galvanic applications with cocain. If simply painful, a fine static spark drawn through the shoe will suffice. In making the static application, a point in the center of the bunion will be found to be anesthetic. Concentrate the sparks at this point until the patient feels the current. This may be repeated once or twice daily. The anodal spark has been used as a rule, but it seems to be the rapid vibrations that are

beneficial, consequently either electrode may be applied with the rapid vibration.

Dysmenorrhea.

The following combination is recommended in painful menstruation in which there is more or less inflammation present:

R. Berberinæ phos.	gr. xii	75
Tinct. hydrastis	3ii	8
Syr. simp., q. s. ad.....	3ii	60

M. Sig.: One teaspoonful every three or four hours.

Where there is ovarian involvement accompanied by dysmenorrhea the following is recommended by *Merck's Archives*:

R. Ichthyol	3i	30
Glycerini	3iii	12
Aquæ, q. s. ad.....	3iv	120

M. Sig.: Douche the vagina with hot water, then apply pledgets of cotton soaked in this mixture as far up as they can be borne and repeat every other day.

Malaria.

The following combination is recommended by V. P. de Sande in *El Med. Titul.* as a substitute for quinin where there is idiosyncrasy against this preparation:

R. Tinct. iodi		
Pot. iodidi, aa	3i	4
Aq. destil.	3iii	90

M. Sig.: One teaspoonful to be taken in a little water at the beginning of the chill and a second dose one half-hour later.

This remedy is said to be of special benefit when administered during the attack when the plasmodium is in the process of multiplication by segmentation.

Chlorosis in the Nervous and Hysterical.

The following combinations are recommended by Yeo in the treatment of chlorosis in nervous individuals:

R. Ferri cit.	3i	4
Pot. bromidi	3iiss	10
Vini (malaga)	3viii	240

M. Sig.: One tablespoonful three times a day.

The following may be taken in the pill form as a substitute for the above:

R. Ferri valerianatis	gr. xx	130
Ext. rhei. q. s.		

M. Ft. pil. No. xx. Sig.: Two to ten to be taken daily.

Methyl Blue in Cancer.

The following formula has been recommended by Cucca and Ungaro, in *Centralblatt für Gyn.*, as a local application in the treatment of carcinoma of the uterus:

R. Methyl blue	3iiss	6
Alcoholis (90 per cent.)	3iii	12
Glycerini	3iii	12
Aq. destil.	3vii	210

M. Sig.: Apply locally to the cervix on tampons following curettement.

The authors state that a weaker solution of the foregoing combination can be used in the form of an irrigation for vaginal and intra-uterine irrigations. By this method of treatment hemorrhage has been checked for months and pain has been so relieved that morphin was not needed to give relief, and the progress of the disease was notably checked.

Chorea.

The following treatment of chorea, as recommended by Professor Comby of Paris, is summarized by *Med. News*:

Absolute rest in bed for at least fifteen days; relative isolation, no games, no intellectual work in order to establish cerebral repose; no wines or other alcoholics, no tea or coffee; only water or milk to drink, combined with a vegetable diet and in case of arsenic treatment absolute milk diet.

The medication is rather striking. He employs two drugs, arsenic or antipyrin; the arsenic is employed in the form of arsenous acid, which is given in frequent doses, very highly diluted, for eight to ten days. The dose of the drug ranges

from one-half a grain (.0030 gm.) to two and a half grains (.15 gm.) daily at the height of the treatment, notwithstanding which the author has only once observed toxic effects. The tolerance, he states, depends on the manner in which the drug is administered, and on the fact that the kidneys are actively stimulated by the ingestion of large amounts of water. If antipyrin is used, he gives as high as eight grains (.50 gm.) at a dose, repeated according to the age of the child.

Ozone in Pertussis.

According to Louis Delherm in an abstract in the *Monthly Encyc. of Pract. Med.*, ozone is a specific in whooping cough and exerts a strong antispasmodic action during the stage of whooping. Given in inhalations of ten minutes three or four times a day it causes marked diminution in the number of paroxysms and seems to prevent recurrence. It decreases cyanosis and seems to aid in the amelioration of a complicating pneumonia. The time between paroxysms is frequently lengthened and the cough is attenuated in intensity, violence and duration. The treatment should be kept up two weeks at least, and it is perfectly harmless.

Medicolegal.

MASSACHUSETTS ACTS AND RESOLVES OF 1902.

Autopsies in Insane Hospitals.—Chapter 417 of the Massachusetts Acts of 1902, entitled "An act relative to autopsies in state insane hospitals and asylums," adds to Chapter 77 of the Revised Laws, entitled "of the promotion of anatomical science," a new section, numbered 5, which reads: Where the cause of death can not otherwise be determined the chief medical officer of the institutions named in section one shall have power to cause autopsies to be made on bodies unclaimed by relatives or friends, before surrendering the same to such persons and in such manner as are specified in Sections 1 and 2 of this act.

Investigations as to Vaccine Lymph.—Chapter 107 of the Resolves of the General Court (legislature) of Massachusetts of 1902 authorizes and requests the State Board of Health to report to the general court as soon as possible a plan for the production and distribution of pure vaccine lymph for free use in the commonwealth; also to report as to the quality of the vaccine lymph in use in the commonwealth during the past winter and at the present time, and as to the quality of the vaccine lymph produced or sold by private persons or corporations in the commonwealth, and the methods and conditions by and under which it is produced. Chapter 121 authorizes and directs the State Board of Agriculture to investigate as to the feasibility and probable cost of producing vaccine lymph at the Massachusetts Agricultural College, for free distribution within the commonwealth, and to report the result of such investigation, together with such recommendations as the board may consider advisable, to the general court on or before January 15, 1903.

Relative to Vaccination.—Chapter 190 of the Massachusetts Acts of 1902 amends Section 137 of Chapter 75 of the Revised Laws by striking out, after the word "whoever," the words "being over twenty-one years of age and not under guardianship," so that it now reads: "The board of health of a city or town if, in its opinion, it is necessary for the public health or safety, shall require and enforce the vaccination and re-vaccination of all the inhabitants thereof and shall provide them with the means of free vaccination. Whoever refuses or neglects to comply with such requirement shall forfeit five dollars." Section 139 of the chapter relative to exemptions is entirely stricken out and the following inserted in place thereof: Any person over twenty-one years of age who presents a certificate signed by the register of a probate court that he is under guardianship shall not be subject to the provisions of Section 137; and any child who presents a certificate signed by a registered physician designated by the parent or guardian, that the physician has at the time of giving the certificate personally examined the child and that he is of the opinion that the physical condition of the child is such that his

health will be endangered by vaccination shall not, while such condition continues, be subject to the provisions of Section 6 of Chapter 44 of the Revised Laws or of the three preceding sections of this chapter; and the parent or guardian of such child shall not be liable to the penalties by Section 136 of this chapter.

Expenses in Smallpox and Other Cases.—Chapter 213 of the Massachusetts Acts of 1902 provides that reasonable expenses incurred by the board of health of a city or town in making the provision required by law for persons infected with the smallpox or other disease dangerous to the public health shall be paid by such person or his parents, if he or they be able to pay, otherwise by the city or town in which he has a legal settlement, on the approval of the bill by the board of health of such city or town; and such settlements shall be determined by the overseers of the poor. If the person has no settlement such expense shall be paid by the commonwealth, on approval of bills therefor by the State Board of Charity. In all cases of persons having settlements a written notice sent within the time required in case of aid given to paupers, shall be sent by the board of health or by the officer or board having the powers of a board of health in the city or town where the person is sick, to the board of health, or to the officer or board having the powers of a board of health in the city or town in which such person has a settlement, who shall forthwith transmit a copy thereof to the overseers of the poor of the place of settlement. In case the person has no settlement such notice shall be given to the State Board of Health, in accordance with the provisions of Section 52 of Chapter 75 of the Revised Laws. No person for whose care and maintenance a city or town or the commonwealth has incurred expense in consequence of smallpox, scarlet fever, diphtheria or other disease dangerous to the public health shall be deemed a pauper by reason of such expenditure.

New Sanatorium for Consumptives.—Chapter 126 of the Resolves of the General Court (legislature) of Massachusetts of 1902 directs the State Board of Charity to investigate the following matters and to report thereon to the general court on or before January 15, 1903: 1. Is it necessary or expedient for the commonwealth to make additional provision for the care and treatment of consumptives? If so, should such provision be made by establishing one large new sanatorium or by establishing several smaller institutions, and, if several, should these be located in different parts of the commonwealth so as to provide for patients at sanatoriums comparatively near their places of residence? 2. Should the patients be furnished board and treatment without charge, or should a moderate charge, not exceeding the actual cost, be made for board? And, if the patients should be unable to pay for their board, should the cities and towns in which they have a legal settlement be required to pay therefor? 3. Where, in the opinion of the board, should a new sanatorium or new sanatoriums be established? 4. What would the board recommend as to the material, plan, manner of construction and details of such sanatorium or sanatoriums? If the board should conclude that it is advisable for the commonwealth to establish a sanatorium or sanatoriums the board is authorized to prepare a general plan of a building or buildings therefor, together with an estimate of the cost of constructing them, and such plan and estimate shall form part of the report to be made by the board to the general court. In carrying out the provisions of this resolve the board may expend, with the approval of the governor and council, a sum not exceeding two thousand dollars.

1. The Urine from Each Kidney.—Valentine finds that Harris and Downes' methods are most applicable to the female bladder, but he thinks that Kelly and Pawlik's methods are easier, safer, and more effective for the purpose, though he admits that he lacks experience. The purpose of his present paper is to recommend Cathelin's divisor which is based on pushing into the bladder a soft rubber membrane which attaches itself to the walls and is grasped by the bladder, thus dividing the viscus into two halves as described in THE JOURNAL of July 19, 1902, p. 173. He reproduces the illustrations and gives details of technic of its management. He has employed it in a number of cases, and its applicability to the general practitioner is, he thinks, shown by the fact that he has found no difficulty in its use after seeing it demonstrated five times.

2. Vaginal Hernia.—Bandler describes the anatomical conditions producing vaginal hernia and describes the various conditions which fall under this head. Out of the broad general class of prolapsus vaginae, he says we must remove the following forms of vaginal hernia: "1. The most frequent, involving the lower half of the anterior vaginal wall, the so-called prolapsus vaginae anterioris, or, better and truly speaking in most cases, cystocele. 2. Prolapse of the upper third of the anterior vaginal wall through descent of the intestines (rare). It is only possible when the union between cervix and bladder has been disturbed. This condition constitutes an enterocele vaginae anterioris. 3. Prolapse of the upper portion of the posterior vaginal wall through a descent of the intestines, or enterocele vaginae posterioris. Here the uterus and the lower half of the vagina are not affected as regards their position. The upper part of the posterior vaginal wall, how-

ever, is influenced by the intestines in the sac of Douglas. 4. A so-called prolapse or dilatation of the lower half of the posterior vaginal wall containing a diverticle of the rectum—a rectocele." The various forms are usually combined. The lateral walls are rarely affected; the most frequently-noted form is cystocele, with descensus uteri. Next is cystocele plus rectocele, the latter due to laceration of the perineum, and least frequent, supposedly, is cystocele alone, though he finds it more frequent than generally supposed. Prolapse of the uterus with invagination of the vagina usually occurs only after the climacteric as the result of senile atrophy of the tissues. Cystocele may recur even with shortening of the round ligament or ventral fixation, and he says that two factors may be stated with certainty: 1. That the cure of retroflexion is not necessary for the cure of cystocele. 2. That the treatment of the posterior wall is not necessary to the cure of the lesion in the anterior wall. He remarks on Theilhaber's surgical treatment by anterior colporrhaphy, extending the excision laterally into healthy tissue, and bringing the upper ends of the levator ani muscle close together, narrowing the vagina and removing the thin urethrovaginal septum, and so closing the space on the under surface of the bladder through which this organ formerly descended. These were the chief reasons of his success. He also, in conclusion, describes elaborately the Dührssen method of ventral fixation as a valuable procedure and of considerable importance.

3. **Yellow Fever.**—Souchon claims that the eradication of yellow fever in Havana is not entirely due to the destruction of mosquitoes, but also to the rigid quarantine instituted by the medical authorities. He holds that yellow fever in a locality exhausts itself in two to four years, provided fresh cases, especially virulent ones, are not brought in from the outside. While he believes in the transmission of yellow fever by mosquitoes as demonstrated by Reed and Carroll, he also thinks there is some other means of transmission, and therefore argues against the mosquito crusade being alone effective. He calls attention to the fact that the same method was much less effectively carried out in other Cuban ports where yellow fever also ceased to exist.

4. **Inebriety.**—Crothers, in his study of the early stages of inebriety, makes prominent the following points: "1. The study of inebriety reveals a well-marked disease, passing through various stages, traceable by many and complex signs and symptoms. 2. The incipient stage seen before spirits are used is marked by dietetic delusions and other symptoms of nerve and brain irritability, all of which seem to depend on heredity or some obscure injury to the nerve and brain centers. 3. A group of symptoms can be found in most cases that may be termed pathognomonic, and will be seen in the later stages fully developed. 4. These early symptoms appear after the first toxic use of alcohol, and in some cases go on to full development, or are held in abeyance by some unknown force. 5. Practically, the recognition and study of this stage opens up a field of prevention and cure that will attract great attention at an early day."

5. **Infectious Bronchopneumonia.**—Wynkoop reports six cases in children and adults which seem to have started by the first cases visiting a watering place, Atlantic City, the others becoming infected. He remarks that the disease is highly infectious in young children. In all the cases there was an absence of coryza at the onset, and only in adults was the severe pain in the back spoken of. The disease in most cases gained its foothold in the larynx, and no amount of carbolic steam inhalations or quinin affected it. Without question it is systemic, the broncho-pneumonia being its local manifestation. The treatment is the same as for ordinary broncho-pneumonia. The prognosis is good, if the case is properly cared for. There is no mental disturbance following as an influenza, and though the temperature may continue high for a time in the convalescence, the general health improves. He suggests that it is inadvisable to send healthy children or adults to any health resort where infection may be obtained.

6. **Diseases of the Gall-Bladder.**—Deaver reviews the various disorders of the gall-bladder, including inflammatory affec-

tions such as cholecystitis, catarrhal, suppurative, phlegmonous, gangrenous, the obliterating forms, adhesions and the relation of these conditions to appendicitis. Cholelithiasis is noticed at length. He thinks the personal history should receive particular attention. He insists on operation as soon as the diagnosis is made. Cholecystotomy is the operation of choice and should be performed as rapidly as possible. There is no need of searching for stones or breaking up adhesions. That can be done later when the danger of infecting the ducts has disappeared. Acute phlegmonous cholecystitis and gangrene also require prompt operation. He disagrees with the view that cholecystectomy is advisable after numerous attacks of cholecystitis with adhesion, etc., and where the gall-bladder is shrunken, contorted or atrophied. He is satisfied as a rule with breaking up of adhesions and leaving the gall-bladder *in situ*. Hydrops usually requires aspiration and cholecystectomy. As regards prophylaxis, he calls attention to the diet, clothing, exercise, fresh air and restriction of the amount of alcohol used. The water cures are beneficial by the regular living and warm baths there used. Surgical operation is the only rational cure for gallstone disease.

7. **Experimental Gastritis.**—Turck has experimented with mustard in dogs to produce experimental gastritis and gives his results. He finds the early appearance of exudate within one or two hours after the introduction of the mustard emulsion, forming later a homogeneous mass of cell debris. The surface epithelium is not affected as much as the deeper mucosa, and the early appearance of necrosed acid or parietal cells, which become granular and lose their nucleus, is noted. Karyokinetic figures appeared within six hours, and cysts of the glands in the twenty-four-hour specimen, with accumulation of leucocytes and degenerated epithelial cells. The exudate becomes infected after a little while, though at first it is not a good soil. He remarks that chemotactic and other effects of mustard due to its peculiar toxic properties open up an interesting point as to what antibodies may be found. He is now experimenting in this direction.

8. **Private Treatment of the Insane.**—Pearce considers that certain forms of insanity are better treated at home than in asylums, though the asylum is best for the majority of cases. His conclusions are: "For all of us the lesson of acute insanities should be modified and retaught, and the earliest possible treatment instituted; looking toward the cure of the acutely insane in private, long before there is any occasion to think of asylum treatment, valuable as that is in chronic insanity, and for the homicidal maniacs and melancholics. Acute insanities of hybrid types, i. e., those that savor of two or more types, are the most hopeful in prognosis, and are therefore the ones to be kept out of asylums to the last moment. Especially where hysteria enters as an element in the case, the patient should be kept out of an asylum. The physician's duty is to overcome the terror felt by lay folk for the insane, and to engender that hopefulness of treatment of such cases in private which is so common in general medical affections."

9. **Widal Reaction.**—The experience in the diagnosis laboratory of the New York Health Department in regard to this reaction during 1891, is reported on by Billings, who finds that cases that showed the positive reaction were all clinically typhoid fever. Of 164 cases where reaction was doubtful, 39 proved not to be typhoid and 33 were typhoid. In 92 cases no subsequent information could be obtained. A number of cases, 78, failed to show a reaction, but afterward proved to be typhoid fever. He remarks on the varied and diverse conditions that may so simulate typhoid as to lead to a Widal test, among them intestinal ulceration, tumor in the lumbar region, hepatic cirrhosis, acute hepatitis, and abscess of the suprarenal capsule. In only one instance was the association of typhoid and malaria noted. A number of specimens were examined also with the paratyphoid test and the results were uniformly negative. He thinks likely that the blood in cases of paratyphoid infection reacts only with the special organism.

11. **The Teaching of Surgery.**—This article by Burrell is the result of a series of inquiries sent out by him to various

institutions throughout the world. He discusses the advantages of lectures, recitations and their use in different institutions. He also enumerates the institutions where surgical anatomy, physiology and pathology are taught as well as surgical technic and diagnosis.

14. Arthritis Deformans.—Bradford discusses the theories of arthritis deformans and concludes that we really do not understand the nature of the disease. It is much more common in old age, and its prevalence is greater than is supposed. He notes a curious fact in the Long Island Almshouse that of a number of old men affected none had nodes in the hands, while in the woman's department, the hands were usually specially affected. Why this should be so is not yet explained. Improvement seemed to follow proper treatment; whatever improves the patient's general condition improves the local symptom. Motion of the joint with protection from sprain improves its condition; improvement will result if contracted joints are straightened and placed in a condition in which moderate motion is possible. Measures to improve the circulation, such as heat and cold and static electricity, are useful. The arrest of the disease by a natural process should be regarded as a stimulus to investigation. He concludes by saying that arthritis deformans may be regarded as an affection of the organs of locomotion characterized by fibrous degeneration of synovial membrane ligaments, bones, cartilage and periosteum, causing an impairment of elasticity, and alteration in shape, and stiffness. These are followed by osseous degeneration, bony ankylosis, and irregular bony deposit. We need more complete pathologic reports of the condition of all the organs in this condition, a thorough investigation of the changes of tissue in the milder stages and carefully recorded clinical facts in regard to the arrest of the affection and the apparent self-limitation, careful chemical investigation of the tissues and blood and excretions. All these are needed before it can be placed on a satisfactory basis.

15. Concentration of Urine.—Sollmann's article is too elaborate for abstracting. He gives special attention to cryoscopic changes.

16. Hip-Joint Disease.—The various methods of treatment of hip-joint disease are reviewed by Young. In some cases, when the ankylosis is of the false variety, multiple myotomies are frequently all that is required, especially when forcible straightening is employed as an adjuvant. Forcible straightening by itself is not sufficient, and may cause great injury if tenotomies have not been performed previously. Osteotomy gives very satisfactory results in true and osseous ankylosis, and its necessity can frequently be determined by skiagrams. The Gant or subtrochanteric osteotomy is better than the Barton or intertrochanteric operation. Motion is not to be expected as the limb is still ankylosed and merely put in a better position. Among the operative measures he mentions aspiration, which has not been found satisfactory, though it may be valuable in small joints. In performing simple incision the surgeon should always have permission to proceed to a more radical operation if necessary. The erosion of the joint after the method of Willard, is favored in all instances when the disease is not extensive, particularly during childhood. This is accomplished by the curettage of every part of the joint surfaces, the debris being carried away by the flow of sterile water through a canulated curette, after which the iodoform emulsion may be thrown into the cavity and drainage provided. All the sinuses should be freely opened as well as all the abscess cavities, and the diseased tissue removed. It is the preferable operation in children, even when the disease is quite extensive, as it does away with the short leg that follows incision of the joint. In extensive disease in adults, incision is advisable, but should only be performed in carefully selected cases. He does not believe in amputation for this condition excepting in rare instances.

21. The Sugar-Controlling Function of the Suprarenal Glands.—In this article Herter discusses the hypothesis of the suprarenal glands serving as a means by which the controlling influence through the pancreatic function of the sugar secretion is exercised. He has put this hypothesis to the experi-

mental test and obtained results which he thinks fully confirm the controlling influence of the suprarenals. In this article he simply intends to indicate the character of the evidence on which the newly-recognized function of the suprarenals is based: 1. Massage of one or both suprarenal glands practiced on dogs is followed by glycosuria. The application of pressure to the gland probably squeezes into the circulation an excess of the blood-pressure-raising constituent of its internal secretion. This is probably responsible for the glycosuria observed, which is largely controlled by the action of this constituent of the cells of the pancreas. Removal of the suprarenal gland or ligatures of its vessels is followed by rapid decline in the sugar of the blood. This does not imply that the removal completely destroys the power of the organism to make sugar, as this is shown to be not the case by experiments. He thinks that the low content of the blood in sugar after exclusion of the suprarenals may contribute to the early death that follows the operation. Sugar is probably required by all the active cells of the organism, and when the supply falls below a certain level it is conceivable that the nerve cells cease to functionate. He also extirpated the pancreas totally four days after ligation of the suprarenal vessels on the one side and ablation of the suprarenal gland on the other, and he finds the results in harmony with the preconception that the removal of both pancreas and suprarenals would render extirpation of the pancreas inoperative in the production of glycosuria. The fact that codein diminishes the sugar secretion in some patients suggested an inquiry as to its method of action, and he finds that it seems to be capable of lowering the blood-sugar content of normal dogs. Whether it acts by uniting with a product of the suprarenal glands is an open question.

22. Intrathoracic Pressure.—Denison's article is largely an answer to Bridge's views that shallow breathing and the passive policy to some extent is better for consumptives, and that they do not so much need altitude as a curative measure. In conclusion he also describes his method of strapping the chest to produce immobility of its lung, which he thinks is possible by this method and is to some extent more advantageous than the Murphy injections.

23. Urethral Strictures.—The following are the conclusions of Greene's article: "1. Careful treatment of chronic urethritis will prevent the formation of stricture. 2. True stricture is of slow growth and can generally be best treated by a prolonged passage of sounds and the proper treatment of any complication co-existent with it. 3. Cutting operations are almost never required in strictures which have not been previously incised. Strictures once incised, unless kept open, are liable to require further incision. 4. An incision being necessary, it is better to do an external urethrotomy combined with an internal urethrotomy if required."

26. Division of the Sensory Root of the Gasserian Ganglion.—Frazier advocates this method of severing the sensory root of the gasserian ganglion in obstinate cases of tic douloureux in preference to extirpation of the ganglion. Its advantages are in the avoidance of hemorrhage from the more severe operation of extraction of the ganglion with the severance of its dural adhesions, etc., and the avoidance of injury to the adjacent structures such as the motor root of the ganglion, the sixth nerve and the cavernous sinus, and reduction in the mortality rate from the operation. Spiller adds remarks on the advantages of the operation, and advises that the sensory root should be divided close to the pons so as to leave no part of the root containing sheaths of Schwann in connection with the pons. This will avoid any regeneration of the sensory fibers that might again bring on trouble.

27. Herpes Zoster.—Joseph finds that herpes zoster forms about 1 per cent. of all cases of skin diseases, and it occurs about equally in men and women. Its age prevalence is usually at between 15 and 30 years, increasing up to that period and decreasing afterward. Before school age it is rare. Its local frequency in the body depends more on the abundance of nerve supply, but there is one exception in his observations and those of Greenough, namely, an exceptionally large number of cases in the trigeminal region. This possibly may be due to the

fact that the region supplied is more open to injury and disease. Both sides of the body are apparently affected-alike or with equal frequency, bilateral herpes zoster being rare. Zimmerleni says that herpes zoster occurs among physicians and nurses in epidemic form, and that no other occupation seems to predispose to the condition. This point can only be verified by consulting industrial and hygienic statistics. Epidemics of herpes zoster occur in the spring and fall and the sporadic cases occur with almost equal regularity throughout the year.

29. Diphtheria Antitoxin.—Fussell reports cases which show the value of diphtheria antitoxin and offers the following rules, which he thinks if followed will reduce the mortality of diphtheria to nothing instead of the present 30 per cent. or thereabout, occurring in Philadelphia: "1. Always make a culture in throat cases; diphtheria can not be certainly diagnosed without it. 2. When called to see a case of sore throat which is doubtful in character, give antitoxin at once and make the diagnosis by culture afterward. 3. When a case of undoubted diphtheria is seen, administer 2000 units at once. If there is no improvement in six hours, administer 2000 units again. Every 12 hours thereafter administer 2000 units until improvement begins. 4. Always give a large dose; 2000 to 4000 units in my hands has proven sufficient, but in desperate cases much larger doses may be used, as proven by the Boston experience. I believe that, given a case of diphtheria in an early stage, it is only a matter of administration of enough antitoxin to effect its cure. If one waits, even in apparently mild cases, fatal pathological changes may occur in the organs which will make death or invalidism certain, even though antitoxin be administered later.

34. Hay Fever.—The method of treating hay fever reported by Goodman consists in first using an alkaline spray to the nose and throat and then the local application of cocain, following these with the spraying of adrenalin, in 1 to 5000. Finally he packs the nostrils with a cotton plug saturated with adrenalin, 1 to 1000, leaving the application in place for ten minutes. He reports cases of his success by this method. While he does not claim it as a positive cure, he thinks the results have been very satisfactory.

38.—This article has appeared elsewhere. See *THE JOURNAL* of October 25, [36, p. 1072.

41. Bacterial Toxins.—In this article Vaughan gives the results of a number of experiments made in his laboratory at Ann Arbor in regard to certain bacilli and their toxins. He describes his method of obtaining toxins, and reviews to some extent the experience of others in the same line of study. He finds that the colon toxin is a constituent part of the cell, and is formed by synthetical processes which build up cell tissues. It is highly resistant both to chemical agents and to heat, and is undoubtedly of complicated constitution, and contains two or more toxic groups, one of which may be split off by agents which have a hydrolytic action. The toxin thus split off from the cell by dilute acids may be deprived of its poisonous property by the long-continued application of heat, especially in the presence of free mineral acid. As regards the anthrax toxin he reviews the work of Conradi and reports that carried out under his direction by J. W. Vaughan, which lead to the following conclusions: 1. The anthrax germ produces an intracellular toxin, which contains two or more toxic groups, one of which is split off by means of dilute sulphuric acid at the temperature of 110. 2. The split toxin is deprived of its poisonous properties by continued heating in the presence of free mineral acid. 3. The toxin split off by dilute acid is probably basic in character and possibly belongs to a low order of proteid substances, since it does not respond to the biuret or Millon test, but does give the xanthoproteic action. It seems, however that this bacillus must undergo certain hydrolytic changes by means of which its toxin is set free. Whether this is a passive one due to normal disintegration of the dead cell or is caused by activity of certain cells in the animal body, is a subject for future investigation. Vaughan says it seems likely that the animal body cells in resisting the invasion of the bacterial cells split the latter up, and in so doing liberate the

poison which destroys the life of the animal. The diphtheria toxin which has been most studied is noticed at some length. He gives the general points of Ehrlich's theory and remarks that Gelston at work in his laboratory has shown in addition to the soluble diphtheria toxin, also an intracellular toxin, and that the commercial diphtheria antitoxin, while it protects animals against the extracellular poison, fails to afford protection against the intracellular toxin. This seems to explain the fact that has been observed that certain animals which are practically immune to diphtheria toxin are not immune to diphtheria infection. Whether or not the antitoxin for the cellular toxin can be produced in animals-artificially, remains to be determined. The relation between the cellular toxin and the soluble poison also opens up a question of interest and importance for future investigation.

52.—*Ibid.*

53.—*Ibid.*, p. 1001.

57. Epistaxis.—The various causes of nose-bleed, including neoplasm, malignant and benign and chronic rhinitis, excoriations, ulcer, etc., are noted and the methods of meeting the cases. The author advises Belloc's method of packing the posterior nares if this is required. If the anterior nares are to be tamponed it can be done usually with gauze in strips one and one-quarter inches wide and six to ten long, crowded back by forceps. No tampon should remain in place longer than three days. He suggests, of course, styptic solutions and adrenalin, though they may be of little service in dyscrasias, where we may use morphin, gelatin injections, saline transfusions, etc. After successfully controlling hemorrhage it will be necessary to examine for constitutional trouble; one should never let the patient alone until the certainty of bleeding is checked. It is advisable to caution the patient as to his mode of living, warning him about blowing the nose too hard, and especially cautioning as to snuffing up water into the nose.

58. The X-Rays.—Duncan has employed the x-ray in a large number of conditions with great success, though in osteosarcoma he has not found it so beneficial. He offers the following conclusions: "1. That while it is not a panacea, and will not relieve all cases of any one kind of lesions, its value as a therapeutic agent is unmistakable and most valuable when properly used. 2. That the sooner the disease is treated after it makes its appearance the more success we may expect. 3. That those scientifically using the treatment should refuse to take patients even when they have every reason to believe they would be benefited, unless the patient can agree to be with the operator at least three or four weeks, for while improvement often is manifested after a few treatments, sometimes it does not show itself for several weeks. 4. That it is often palliative in inoperable cases and rids the patient, if only temporarily, of great pain. 5. That after an operation for a malignant growth the healing of the wound by the x-ray is beneficial, in that diseased tissue which probably may have escaped the knife is destroyed by the ray during the healing process. 6. That the operator must especially understand his tubes and not indiscriminately use tubes of great and slight resistance. 7. That sufficient time has not elapsed for us to say that the lesions will or will not return; but suppose they should return in six or twelve months or a longer time, is it not easy for the patient to undergo the same treatment, and probably get the same relief? Thus far, however, I may say that relapses have been very rare with those who have used the treatment longer than I have. 8. That in superficial epithelioma, lupus of both forms, especially vulgaris, cancer of the breast, and sarcomas of some forms (not osteo), the ray is very beneficial, and in the great majority of cases curative. 9. That in the treatment of cancers of internal organs judgment must be suspended until further experience and perfection of the apparatus."

59. **Pleurisy.**—Hunter holds that at least 50 per cent. of the cases of pleurisy are tuberculous, judging from his study of the literature and his personal experience. He does not consider it, however, necessarily gloomy in prognosis as a pulmonary affection is not inevitably the result. He advises climatic treatment in tuberculous pleuritis, and thorough anti-tubercular régime. Cases in which it is a question of removal of an effusion are sometimes puzzling, but the effusion is frequently more or less rapidly absorbed. When the dyspnea is not urgent and the cardiac impulse in normal position, it is prudent to wait, although the quantity of fluid may be quite extensive. The restriction of fluids and the use of saline cathartics, diuretics, massage and "flying" blisters may be tried. He quotes the following indications for paracentesis from Fowler: "1. When there are signs of positive intrathoracic pressure; 2, when the following symptoms which usually accompany the above condition are present—a small, irregular pulse and urgent dyspnea, palpitation on slight exertion, lividity, or evidence of engorgement and edema of the opposite lung. These symptoms may, however, be absent in cases accompanied by positive intrathoracic pressure so long as the patient is lying perfectly still. 3. When the fluid has been ascertained to be purulent its removal is necessary in all acute cases. It may be necessary to remove the fluid more than once, but only a few repetitions can be borne by the patient without impairing his strength. In aspirating, strict antiseptic precautions must be observed. The needle or the canula—if a trocar be used—should be about one-tenth of an inch in diameter and about three inches long." The usually selected positions are between the sixth and seventh ribs in the mid-axillary line or between the ninth and tenth, just outside the line of the angle of the scapula. The fluid should be withdrawn slowly and careful watch be kept on the action of the heart and the respiratory movements.

64. **Sterility.**—The various causes of sterility in women are reviewed, including displacements, cervical constrictions, operative procedures, etc. Ovarian disease is also considered and Ill thinks that an abnormal thickness of the tunica albuginea is also a cause. He remarks in regard to Polk's recommendation of operation on the ovaries and adnexa for sterility that he thinks it has opened up a vast field of usefulness in surgery.

68.—This article has appeared elsewhere. See abstract in *THE JOURNAL* of October 4, p. 854.

69.—*Ibid.*, see *THE JOURNAL* of October 11, p. 916.

70.—*Ibid.*, title 74, p. 1005.

72. **Appendicitis.**—Greene claims that palpation is the first and most important procedure in making the diagnosis of appendicitis. As regards the actual acceptance of the case for life insurance, it would seem that the following rules might reasonably be laid down: Cases of non-suppurative appendicitis where the appendix has not been removed and primary union obtained, might be accepted after six months from the time of operation. Cases where no operation has been performed might be acceptable after an immunity from all symptoms for two to five years. Suppurative cases in which drainage has been established without removal of the appendix might be acceptable after two years of immunity from symptoms, and where the appendix has been completely removed, after one year. Cases of unoperated suppurative appendicitis with spontaneous rupture and bowel drainage may be acceptable after three years' immunity, and cases where there has been general peritonitis may be considered acceptable one year after the appendix has been successfully removed; after five years with complete immunity and restoration to health if recovery has been due to simple drainage operation. If treated medically it would be safer to require at least five years' immunity in all cases. These recommendations are based on the favorable report from the medical examiner and a substantial extra premium would be necessary if fistula or ventral hernia were present at the time of examination. Occupation ought to be a factor of importance if there is liability of strain.

73. **Race and Mortality.**—Hoffman reviews the United States census reports, giving tables of the comparative mortality of the white and colored population, showing a nearly

double proportion in the latter, and of the native and foreign white, while the native stock seems to have a decided advantage at most ages above infancy. The comparative mortality of the principal nativities is also tabulated, which shows that outside the negro population the greatest death rate appears in the Irish and German, while the Polish show a comparatively small ratio. A comparative mortality from specific disease shows the same approximate ratio between white and colored in consumption, pneumonia and typhoid, excepting in the white females where the typhoid mortality is greater than among the colored. Cancer seems to have its greatest mortality among the Germans, Irish and Italians. The mortality from disease of the female generative organs is highest among colored women, followed by Italian, the Poles showing the lowest rate. Affections of pregnancy, or the results of childbirth, caused the highest relative mortality among the Italian women. He concludes that race and nativity materially modify the mortality and special disease liability, but further observations and investigations are required before it will be possible to establish general laws useful for life assurance purposes. He concludes with the suggestion that insurance examiners can do no more important service than by occasionally contributing observations of their personal experience with cases of different nativity or parentage.

85. **Leucocytosis in Lead Workers.**—Boston finds that the patients in the Philadelphia hospitals from various lead works show a leucocytosis ranging from 4000 to 25,500 cells per c.mm. The average number of leucocytes in this series was 12,600. He reports in detail the blood examinations with brief remarks as to the general clinical pictures.

86. **Hemorrhage in Typhoid.**—The exact etiology of hemorrhage is hard to explain. Curtin has never seen it in very young children, and he thinks that there are conditions other than anatomic ones that exert some influence on the escape of blood from the blood-vessels. As instances, he reports cases where mental emotion seemed to stop the hemorrhage. The pathology, of course, is erosion in the intestinal canal. In diagnosis the first requisite is to have on guard some one competent. He had a nurse once who took the subnormal temperature due to internal hemorrhage to be a favorable sign. When hemorrhage ceases the temperature usually rises again nearly to its former height, and in some cases even higher. He thinks that often, even with severe symptoms, the patient may recover; the prognosis is not a hopeless one. The associated conditions that seem to be most serious in the severe cases are given by him as follows: "1. Renal disease, which sometimes alters the blood, in some cases rendering it less coagulable and thus favoring hemorrhage from all points. 2. Marked organic heart disease, in which the blood, being impoverished and lessened in quantity, is propelled slowly, causing the tissues to be only imperfectly supplied with blood. Under these circumstances, a hemorrhage from the bowel becomes a most grave complication. 3. Hemophilia, in which the blood becomes so altered there is little likelihood of the hemorrhages being staunched and much liability to other hemorrhages. 4. A tympanitic distention of the abdomen with the continued discharge of black, clotted blood, which is a very serious condition, as the blood-vessels are kept patulous by the distention of the intestines; or the latter and the blood-vessels have both lost their contractile power, thus favoring relaxation, not only of the bowel, but also, of the walls of the blood vessels. I always dislike to see this condition in hemorrhage from the bowels. 5. Obstinate diarrhea and vomiting, which are decidedly unfavorable to the staunching of the blood." He has found the usual remedies to be of more or less value, and he has great faith in turpentine externally and internally. He also recognizes the advantage to be derived from suprarenal extract internally, and in extreme cases he has seen the efficacy of placing ligatures around the limbs during hemorrhage. He concludes with a quotation from a paper read by him on the statistics of 60 cases before the American Medical Association in June, 1897.

87. **Abdominal Pain in Typhoid.**—The causes of abdominal pain, colic, distention, enterocolitis, ulceration, phlebitis, appendicitis, ileus, septic peritonitis, etc., are noticed by Allyn,

with their special symptoms. He thinks we need more information as to the premonitory symptoms and a keener appreciation of pain as a danger symptom. Leucocytosis needs special consideration. He insists that pain and tenderness are not necessarily accompaniments of typhoid fever; on the contrary, they may be signs denoting the approach of actual onset of cholecystitis or perforation. Pain is frequently a danger signal. It should lead to a more careful study of the cause, more frequent visits and a careful record of the observations. Where there is reason to suspect cholecystitis, perforation or peritonitis the surgeon should be called in.

88. The Diet in Typhoid.—Robertson discusses the various ideas in regard to diet and holds that the food is not responsible for recrudescence and relapse in this condition. We should not withhold it on this basis. No matter what treatment has been adopted, the mortality is not materially increased, as shown by statistics. He quotes from Fitz, Bushuyev, Sartsievich and Shattuck as to the advantages of a more generous diet. The objections to it are necessarily theoretical, but, judging from the published reports, the death rate from the well fed is a little less than those on a liquid diet, but the prevailing type of disease must be the chief factor. He says free feeding will undoubtedly serve to diminish the number of deaths from asthenia and infection due to lessened resistance.

89. Typhoid Perforation.—The dangers of typhoid perforation may be attributed mainly to two causes: 1. Delay in operating, chiefly on account of imperfect diagnosis. We should study our cases more and be able to diagnose the disease quickly. 2. To surgical errors of judgment and technic. Le Conte discusses this subject under four headings: 1. Shock. He disagrees with surgeons who hold that when shock is present operation should not be undertaken for some hours later or until reaction has occurred. Every hour that the perforation remains open the greater the danger from leakage and the larger the extent of peritonitis. Therefore, operation should be immediately undertaken. 2. Incision. In 85 or 90 per cent. of cases the perforation will be found in the last 20 or 30 inches of the ileum, or in the cecum or appendix. In 10 or 15 per cent. other portions of the small and large intestine, notably the sigmoid flexure, which after the cecum is the most likely place to look for perforation. Le Conte's rule, therefore, is to make an incision directly through that portion of the bowel most likely to be affected, namely, in the right semilunar line below the umbilicus, and at once expose the head of the colon. Starting at this point the last three or four feet of the ileum are examined, next, the cecum and appendix, and then the ascending colon as far as it can be exposed. If no signs of peritonitis are discovered, he would consider that an error in diagnosis had been made and discontinue further operative interference. If, however, peritonitis is found to be present, but perforation is missed, he would continue the search by making a median incision, examining the sigmoid flexure, descending and transverse colon, and then the remaining small bowel in the order named. We should remember that the perforation may be completely hidden from sight by lymph, and, therefore, all areas that are indurated or covered with lymph should be most carefully examined. When the perforation is of such a size that the closure of the opening will not produce a too marked stenosis of the bowel, it should be sutured at once, either transversely or longitudinally to the lumen, whichever way produces the least narrowing of the tube, and no time wasted in paring the edges of the ulcer. A running Lembert suture is not advisable as it might tear out; an interrupted Lembert mattress suture is best. After closing the opening other perforations should be looked for, as in 17 or 18 per cent. the openings are multiple. Dark necrotic spots should be treated as though perforation had taken place, and the weakened areas folded in with sutures. If simple closure is not practicable on account of the size of the opening, the condition of the bowel, or the number of perforations, several methods are open. 1. A plug of omentum may be fashioned to fit the opening, held in place with stitches, not as a patch is applied to a garment, but like a cork in a bottle. He has seen this done by Nature's processes alone. 2. Resection of the bowel. This is a long operation and a severe one,

which is against its success. 3. The formation of an artificial anus. This would only be practicable in a single perforation, and might require a second dangerous operation to close the opening. If this is chosen, the bowel should be stitched to the muscle or fascia, and not to the skin of the abdominal wall, so as to favor as much as possible a later spontaneous closing of the opening. 4. Cutting off the damaged area of the intestine from the general peritoneal cavity by walls of gauze. This imitates Nature's method, requires but a short time, and can be done with ease and a large area of bowel can be isolated. In this way he has walled off the last two feet of ileum, cecum and part of the ascending colon with perfect success. Some portions of the bowel gave way the next day, with the formation of fecal fistula, but at the end of four weeks the openings spontaneously closed. He would prefer the plug of omentum in a very limited number of cases, where it is applicable, and for the others, walling off with gauze, leaving resection of the intestine or the formation of an artificial anus for the exceptional case. In rare cases where the perforation has produced a well-walled-off abscess, as seen in appendicitis, if the incision through the abdominal wall opens this cavity, he would be content to institute drainage, after gently sponging the cavity, and not attempt to find and suture the opening. If, however, the anterior abdominal wall does not form a part of the abscess wall, the tumor should be walled off with gauze, the adhesions broken open and the perforation sought for and dealt with radically. Short operations are generally well borne, but long ones are usually fatal. He gives the details of the peritoneal toilet and drainage, careful cleansing of the infected coils, etc. He thinks that flushing the whole abdominal cavity with limited signs of peritonitis, is dangerous as it may disseminate the infection. He, therefore, prefers cleansing limited areas in the abdomen with dry sponges, trusting to proper drainage to prevent further spreading of the infection. When the peritonitis, however, is extensive a copious douche must be resorted to. The cavity must be flushed with large quantities of hot water while the intestines are outside, while the hand gently stirs the water round to bring it in contact with all the peritoneal surface. The intestines are then douched and cleansed outside the abdomen and returned, and free drainage is instituted. In closing the abdomen only such sutures should be used as are necessary to keep the intestines in their proper place. The rest of the wound should be filled with gauze to secure the best possible drainage. It is his custom to raise the head of the bed to aid the fluids to gravitate to the pelvis. He thinks that delay is far more responsible for mischief than surgical errors in judgment.

92. Urinalysis.—Crismond insists on the importance of the urinalysis, paying special attention to the cleanliness of the utensils, examining 24-hour samples and the importance of the quantitative test by the centrifuge. This, in addition to a microscopic examination, makes a scientific diagnosis.

94. Filariasis.—Austin reports a case in a physician aged 53 who had been a resident in the country for 40 years, with no record of foreign travel. The diagnosis was ptomain poisoning, but careful examination of the blood revealed the sheaths of embryos of the *Filaria sanguinis hominis*. He thinks he had in the case not only the involvement of the kidneys, but also some parenchymatous vascular changes in the liver.

95. Adrenalin.—Campbell reports three cases of the use of adrenalin chlorid in 1 to 1000 solution, 15 drops three times a day internally, for profuse uterine hemorrhages following polypi or fibroids. Other remedies had failed, but this was satisfactory from the very beginning of treatment.

97. Sub-Conjunctival Inflammations.—Gradle describes what he thinks is a not altogether rare lesion—hitherto not definitely named—consisting in a patch of inflammation in the sub-conjunctival tissue over the eye-ball and not quite identical with episcleritis. It is irregular in size and shape, inward and outward from the cornea, oftener below than above the horizontal meridian, more commonly single than multiple, is slightly but distinctly swollen and marked by congested conjunctival vessels, beneath which there is a variable injection of the deeper vessels of a violet hue.

between it and the corneal margin; more rarely it extends to the limbus and ends abruptly with a steep change of level. The marginal inflammation may be mistaken for circumscribed symptomatic ciliary injection. It differs from typical episcleritis by being distinctly more superficial, not nodular, and leaving no slaty discoloration, and, as a rule, yields better to treatment. There are, however, transition forms between the two. Symptoms are limited to irritability and weakness of eye, varying with the intensity of the inflammation. It may be a manifestation of serofulous ophthalmia, but is more often, in adults, due to acute conjunctivitis inefficiently treated. He has also seen it occur as a vesicle, probably a herpes febrilis; he has also observed it in a relapsing form in diabetes. It has been described also in its relapsing type by Graefe as "subconjunctivitis," by Hutchinson as "hot eye" and by Fuchs as "episcleritis periodica fugax," due to rheumatism, malaria, and often to unknown causes. The non-relapsing or non-recurring type here noticed seems to have been undescribed.

107. **Hyperchlorhydria.**—Stucky finds that hyperchlorhydria exists as the result of a primary lesion of either the liver, spleen, pancreas, and sometimes of the kidneys, and that while it does occasionally occur as a neurosis, it is a rarity. In the majority of cases it is a secondary affection due to organic or functional lesions in some part of the body and may at times be associated with some constitutional affection.

108. **Inebriety.**—This article is similar to §4, which see. The etiology must be studied by medical men from the physiologic point of view and only with long-continued and accurate observation can it be understood.

FOREIGN.

Titles marked with an asterisk (*) are abstracted below. Clinical lectures and single case reports are omitted unless of exceptional general interest.

British Medical Journal (London), October 18.

- 1 Introductory Address at the Opening of the University College, Liverpool, "A Modern Religio Medici." Frederick Treves.
- 2 *On Exaltation of Bacterial Virulence by Passage Outside the Animal Body. E. W. Ainley Walker.
- 3 Recent Progress in the Housing of the Insane. George W. Mould.
- 4 A Discussion of the Treatment and Care of Persons in the Early Stages of Unsoundness of Mind. John Sibbald.
- 5 The Hospital Treatment of the Insane as Carried Out at the London County Asylum, Bexley. C. Hubert Bond.
- 6 *A Discussion on the Relation of Neurasthenia to Insanity. T. Clifford Allbutt.
- 7 *On Apprehensiveness, Stupor and Katatonie. Robert Jones.
- 8 *A Discussion on Syphilis as a Cause of Insanity. F. W. Mott.
- 9 *Action of Heroin and Dionin on the Respiration. C. R. Marshall.
- 10 The Digestibility of Fats and Oils, with Special Reference to Emulsions. John W. Wells.
- 11 *Synthetic Purgatives: The Purgative Action of Dihydroxy-Phthalophenone (Phenophthalein, Purgin). F. W. Tunnicliffe.
- 12 The Therapeutic Value of Arsenic and the Justification of Its Continued Use in the Light of Recent Observations Concerning Its Toxic Action. Ralph Stockman.
- 13 Arsenic in the Treatment of Chorea. Frank M. Pope.

2. Increase of Bacterial Virulence in Vitro.—In this seventy-second report of the Scientific Grants Committee, Walker reports experiments on the increase of virulence of bacteria by repeated artificial cultures in the test tube. The typhoid bacillus was used and the tests of virulence were made on guinea-pigs. Necropsies were performed on all the animals that died and the organism found examined microscopically and culturally to ascertain its identity and presented the characteristics of the *Bacillus typhosus*. Comparisons were also made of the relative number of bacilli in the emulsions. The conclusions reached were that the virulence of the bacteria may be increased by passage through the bacteriolytic fluid *in vitro*. The practical bearing of these observations and their relation to certain of the problems of infection and immunity are apparent. The increase of bacterial virulence which may be brought about by passage through the body of the living animal is probably attributable to the effect of the successful resistance of surviving micro-organisms to the bactericidal action of the living tissues.

6. Neurasthenia and Insanity.—Allbutt gives a theory of neurasthenia that it is an individual weakness by which exhaustion takes place over repair and a lowering of the nervous potential with imperfect recovery. He contrasts it with hysteria, which is a special abnormal interference with special inhibitions. Hypochondriasis is not a step between neurasthenia and insanity, nor is it insanity, though close to it. It consists in a fixed idea which seems to closely approach delusion, but does not cross the narrow line as often as might be expected. Neurasthenia with obsessions he is inclined to think is nearer insanity, especially when they are such as an internal call to do some wrong or to satisfy some morbid desire are they more characteristic of insanity than neurasthenia. The relation of neurasthenia to insanity requires close attention to diagnosis and he distinguishes the early stages of melancholia or delusional insanity or general paralysis which may simulate it very closely. Unlike some other authors, he remarks that the memory in neurasthenia loses its tenacity, the attention is enfeebled, but sharply defined breaches of memory are more characteristic of hysteria or epilepsy, and he has never seen them in neurasthenia. Depression of spirits, if primary and persistent, is more characteristic of melancholia or hyperchondriasis. Of late years he has observed a sort of post-operative neurasthenia following certain operations, not always severe ones, more common in women than in men. It is very like the neurasthenia of railway cases, and whether due to the anesthetic or the mental strain, etc., is hard to say. He mentions it to ask if this post-operative neurasthenia is some lingering phase of an earlier acuter disturbance known as post-operative insanity.

7. Katatonia.—Jones considers katatonia not as a separate type, but as a special syndrome in other forms of insanity, more especially the cyclic forms. In his experience it almost invariably is preceded by a period of apprehensiveness, which is itself preceded by irritability, headache or pain, and a sort of panophobia. This is followed by a condition of muscular tonus and stupor. This apprehensiveness with high muscular tension means low blood pressure, and probably also means a diffusion of nerve power, and an absence of volitional control. He has studied cases as regards the blood pressure and finds it varying from 80 to 110 mm. of mercury. It indicates a corresponding impairment of the general metabolism. In some cases marked excitement alternates with the stupor, the change sometimes being sudden. The tendency is generally toward dementia. He speaks particularly of the moral causes, together with over-pressure in education, etc., in its etiology. Its pathology is probably a special form of nutritional impairment in the neuron. The swollen nucleus with granular degeneration of the Nissl bodies, the disappearance of fiber plexuses, and the changes in the deeper layers of the cortex, caused by the destruction of the neurons and increase of the glia tissue, which are described as the pathologic appearances in cases of katatonia, may help us to account for the symptoms.

8. Syphilis in Insanity.—Syphilis may cause insanity, according to Mott: 1, by moral shock; 2, by the effect of the poison and anemia on the general nutrition; 3, the specific poison may cause inflammation affecting the enclosing, supporting and nutritive tissues of the brain, producing meningitis, usually basal, gummatous tumors, endarteritis and periarteritis. Most of these cases occur in young males within four years after infection, and they frequently run a rapid course in spite of treatment. The severer forms closely resemble general paresis, but he points out certain differences: The coarser paralysis and the involvement of special cranial nerves, nocturnal headache, tenderness on percussion, etc. Perhaps pseudo general paralysis is an applicable term, but syphilitic brain disease is, he thinks, the best, for, of all the forms of insanity, this may be looked on as a special organic brain disease with mental symptoms: Moreover, it is one of the most amenable to treatment of all the severe forms of insanity. 4. Syphilis is a cause, and a very potent one, of arterial degeneration, arteriosclerosis. 5. He raises the question as to the relationship of syphilis with general paresis and adduces the usual arguments in favor of this connection. He remarks that he

has never seen a general paralytic with a primary sore or secondary eruption among the many hundreds he has examined, and considering the frequency with which these expose themselves, he thinks this can be best explained by the immunity afforded by the previous infection. In order to excite discussion he affirms the proposition, "no syphilis, no general paralysis."

9. Heroin and Dionin.—The action of heroin and dionin on the respiration is studied experimentally by Marshall, who employed anesthetized rabbits with the tambour method to show the changes. He finds that heroin can prolong inspiration and increase its depth, but the results of its beneficial action are very soon past and slowing is ultimately produced. Dionin appears to be slightly more sedative than codein, but otherwise has the same action. Heroin has a much greater effect on the respiratory center, but he doubts whether this will prove of much use therapeutically. The results of its beneficial action are too narrow.

11. Phenolphthalein, Purgen.—The purgative action of this substance was apparently found accidentally. Phenolphthalein being considered a harmless drug, was used by the Austrian Government to earmark a certain class of wines, and the resulting diarrhea produced in the drinkers called attention to this action of the drug. The purgative action is much more marked in man than in animals, which is credited by Vamossy to the fact that in the latter the conversion into sodium salt either does not occur or only to a very slight extent. The conclusions reached by the author are: "1. For children, phenolphthalein in doses of from $\frac{1}{4}$ to $2\frac{1}{4}$ gr. (one to three tablets of infant purgen) is a useful aperient. 2. For ordinary adults, this drug must be given in doses of from $1\frac{1}{2}$ to $4\frac{1}{2}$ gr. (one to three tablets of adult purgen). 3. In cases of obstinate constipation, the dose must be increased to 15 gr. (one to two tablets of strong purgen). 4. Phenolphthalein produces purgation in jaundice. It has no irritating action on the kidneys; its depressant action on the circulation is less than that of magnesium sulphate."

18. Urea in Tuberculosis.—Harper gives a lengthy tabulation of cases in which his treatment of tuberculosis with urea was employed, and he says it fulfills many of the requirements. It is not corrosive, can be given in sufficiently large doses, and is not a substance foreign to the economy. He begins with 20-gr. doses, and gradually increases up to 80, 90 or 100, three times a day between meals. If any gastric symptoms appear he discontinues it for a few days and begins again. Only pure urea should be used, as the commercial form used in dyeing causes vomiting and diarrhea. He calls attention particularly to the fact that 3 per cent. of pure urea added to a virulent culture of tubercle bacilli in an incubator kills the organisms. In mixed infection he gives along with the pure urea, calcium sulphid in $1\frac{1}{2}$ and 2 gr. pills, four or five pills daily for any of the streptococcal infections. In proportion as he has increased the nitrogen in tuberculosis, the death rate has lessened. During the last twelve months he has only signed one-fourth as many death certificates as compared with two years before.

24. Mouth Bacteria.—In this second lecture Roughton discussed the toxic bacteria in the mouth, calling attention to the fact that saliva has long been known to be at times poisonous, and mentioning the infection which has been known to follow dental operations, pyorrhea alveolaris, etc., various forms of stomatitis and the relation of oral bacteria to the disturbances of digestion, pulmonary infection, infection of the cervical glands, etc. He quotes Dr. G. W. Cook, Chicago, as to the existence of tubercle bacilli in carious teeth. Other infections are mentioned, as are also the dangers of infection of the mouth as a source of infection to others.

25. Psoriasis.—Watson and Thompson recall that on March 22 one of them reported to the *British Medical Journal* the description of a preparation of bone marrow to which the name myelocene was given and the results which had been obtained with it in chronic ear disease. They publish the present article to record the results obtained by the treatment of psoriasis with this substance and report a number of cases. They say from the facts they feel justified in concluding that

myelocene contains a substance of distinct therapeutic importance for the treatment of psoriasis. Even this small number of cases here reported appear to warrant the conclusion. Certain constitutional symptoms, however, must be recognized, as toxic symptoms will undoubtedly follow the unskilful use of the substance. The questions which arise will be how far the dietetic and other conditions are unfavorably suited to the production of the vital substance, which is a therapeutic agent in myelocene, and 2, what alterations must be made in these conditions with a view to the production of this necessary constituent. In conclusion they lay special stress on the following points in the observation and study of psoriasis: "1. A careful examination, frequently repeated, of the stools, more especially as to the odor and consistence, with the view of determining to what extent the intestinal canal may be acting as a focus of absorption of toxic substances. 2. A similar investigation of the urine, especially noting the total amount passed daily, so as to supply evidence as to the renal activity and general cardio-vascular tone. Further important evidence on this latter point is obtained from (3) a study of the capillary reaction of the general skin surface. More information may sometimes be gained from a critical examination of the skin that is apparently healthy than of the skin that is obviously diseased."

40. Treatment of Vicious Ankylosis of Hip Joint.—Resection of the joint, or osteotomy of the neck of the femur exposes to the danger of arousing the tuberculous or pyogenic process, if it is not entirely extinguished. Vincent's method of treating vicious ankylosis of the hip joint consists in sawing the femur

across and fitting it in a niche made for it in the postero-inferior surface of the great trochanter. The soft parts are incised down to the bone for 12 or 15 cm., commencing at the farther end of the great trochanter, and turned back. The niche is then cut in the trochanter as wide as the diameter of the femur and about one centimeter deep. The femur is then divided at the line shown in the cut and is brought down and fitted into the niche as a carpenter fits a tenon into a mortise. The femur is then vertical instead of more or less horizontal, and the flaps of periosteum are fitted over the raw parts. Cp. in the cut means collar of periosteum reaching to the dotted line, left after the femur has been removed. The wound is drained through a counter-opening at the lowest point as the patient reclines. A cast is applied to immobilize the limb in extension and slight abduction. The fitting of the femur in the niche prevents all slipping and dispenses with a suture and the consequent danger of osteitis around foreign material. Implantation of the femur at this point diminishes the shortening of the limb by the entire width of the trochanter. No disturbances in the circulation need be apprehended, and as the field of operation is remote from the focus of preceding inflam-

mation in the joint, there is no danger of arousing it. The results are functionally perfect in the two cases that have been followed for twelve and two years. The limb has been straightened, the shortening reduced to the minimum and the solidity is perfect. Another case illustrates the benefit to be derived from application of Lorenz's screw in the course of osteotomy undertaken on account of a diaphysal fracture of the femur with pronounced chevauchement. The screw confers great power on the surgeon, with a convenience and precision far superior to manual traction. The patient was a lad of 14 who had been run over, sustaining a fracture of both femurs. After two and a half months of weight traction the ends of the bones still rode each other by 9 and 5 cm. The chevauchement was rapidly overcome with Lorenz's screw, and half the width of the end of each stump was cut out, forming two steps which fitted into each other as the bones were coaptated by the screw. He calls this the Z resection, or the "steps" (escalier). The stumps fit into each other and there is no further necessity for extension as the stumps hold each other in place. Vincent concludes by calling attention to the fact that many cases of supposed traumatic arthritis and peri-arthritis are in reality unrecognized fractures of the joint. They require what he calls a "cotton-silicate bandage" (ouato-silicaté) which soothes the pain, tends to diminish the effusion and prevents inflammation. If arthrotomy and suture are inevitable, he advises restricting the suture to the para-ostal parts rather than to introduce a foreign body into the bone itself. His article is profusely illustrated.

10. **Massage of the Exposed Heart.**—Schiff proposed in 1874 to open up the heart and restore its spontaneous action by rhythmical compression of the ventricles, but it was not until 1892 that surgeons conceived the idea of applying this so-called massage of the heart to the resuscitation of persons dying under chloroform. Boureau has been able to collect a dozen cases in which this has been attempted. The surgeons always reached the heart by resecting ribs and opening the pericardium through the pleura, until Poirier recently entered through the diaphragm. The patient having succumbed in the course of a laparotomy, he tore the diaphragm and massaged the heart through this opening from below. Maclaure also reached the heart through an incision in the diaphragm in a case recently reported. This route avoids the dangers of pneumothorax. In Tuffier's patient after rhythmic compression of the heart for two or three minutes, reached through the pleura, the organ began to contract, the patient sighed, the pulse reappeared, the pupils contracted and the wound was tamponed. After sighing a few times the pulse vanished again, but was again restored by renewed rhythmic compression of the heart, and the circulation was re-established for a few minutes, after which it subsided and could not be started again. It is possible that such maneuvers might succeed if they were done earlier. They have never yet been successful in the actual resuscitation of any person, although Prus and Batelli have succeeded on large numbers of dogs, especially after applying an alternating 240-volt current or a powerful electric discharge.

11. **Post-Operative Hydatid Grafts.**—Dévé states that both clinical and experimental data show that the scolex and the capsule as well as the daughter cysts may generate new hydatid cysts. In his experimental research the vitality of these hydatid germs could be completely destroyed by contact for 2.5 minutes with a 1 per 1000 solution of sublimate or a .5 per cent. solution of formol. He, therefore, suggests as a preliminary measure in ablating an echinococcus cyst to inject a parasitocidal .5 per cent. solution of formol and leave it in contact with the contents of the mother cyst for two or three minutes before attempting to remove the cyst.

12. **Long Incubation of Rabies.**—Kasperek has collected 22 cases of long incubation in the literature. They include 17 from 8 months to nearly 3 years; 2 at 5 years, and one each at 10, 18 and 20 years. In the case personally observed the child was bitten on the hand and arm and was taken at once to Vienna for Pasteur treatment with the other children bitten by the same dog, which was known to be rabid. Hydrophobia

developed seven months afterward; all the other children have remained healthy to date.

24. **Transmission of Human Tuberculosis to Cattle.**—Fibiger, of Copenhagen describes 5 cases of primary tuberculosis of the intestines, including 2 in children. Inoculation of calves with bacilli from them showed that the microbes were harmless, slightly virulent, virulent or extremely virulent in different cases. This ascending scale corresponded in inverse ratio to the duration of the affection and the age of the subjects. It is possible that the bacilli become less virulent for cattle the older the process in the human subject. This coincidence of primary tuberculosis in the intestines and the virulence of the infection for calves seem to suggest that they were cases of actual bovine tuberculosis in man.

38. **Ligature of Arteries as Palliative Treatment of Carcinoma.**—Krönig has operated on three patients with carcinoma of the uterus in an advanced stage by ligating the ovarian and hypogastric arteries on both sides. All hemorrhages ceased at once afterward, although they had been of daily occurrence before. In one case a hemorrhage recurred three months later, probably from the establishment of collateral circulation. The flow of pus was only temporarily suspended. It might be possible to combine excochleation of the carcinomatous masses with the ligatures. He ligated the hypogastric close to the common iliac artery, and the ovarian as it entered the broad ligament. In future he intends to ligate also the artery in the round ligament to prevent collateral circulation. Only a very small incision in the abdomen is required. He recommends in all cases of abdominal operation for the removal of uterine cancer, when the neoplasm is found inoperable, to ligate the arteries as described, before closing the wound. It can be done in five minutes.

46. **Prophylaxis of the After-Affections of Syphilis.**—Cohn regards tabes and progressive paralysis as the necessary result of the accumulation in the blood of the living bacterial and dead toxins from the latent neoformation of the syphilitic poisons. Mercurial treatment is of no avail at this stage and does only harm. The toxins have an elective action on certain portions of the nervous system after accumulating to a certain amount in the blood. This progressive, specific dysemia is apparent in the complexion of syphilitic subjects in the incipient stages of tabes. He suggests that it might be possible to ward off these after-affections by periodical, repeated venesection at long intervals. Withdrawal of a certain amount of blood would free the body from the toxins contained in it, and the new blood that would be produced to take its place would take up the struggle against the bacteria with fresh energy and an increased elimination of toxins would follow. As this measure of systematically repeated venesection would be harmless, he thinks that when the organism is once saturated with the syphilitic poison, it is our duty to employ it. He believes that it might be possible to induce local immunity against the primary infection by prophylactic local mercurial inunctions, systematically repeated at intervals, supplemented by mechanical and mercurial measures after possible infection. He also advocates multiple small injections of mercury in a circle around the primary lesion when it first develops. It is possible that the mercury may follow the germs into the glands and annihilate them there, in addition to its effect on the lesion itself. And when the disease is once thoroughly established the accumulation of the poisons in the blood must be combated by systematic blood-letting at certain intervals.

51. **Gangrene After Subcutaneous Infusion.**—Wormser replies to the communication from Baisch in Nos. 35 and 36 of the *Deutsche Med. Woch.*, reviewed in THE JOURNAL at the time, to the effect that the gangrene of the skin observed after subcutaneous infusion of Tavel's solution is not due to this fluid, as he has observed it after infusion of normal salt solution, and Welch, Bloodgood, and Zimmermann have reported similar cases in which only the normal salt solution was used. Brocq has observed cases of gangrene of the skin after injections of gray oil. [Tavel thinks that an artificial serum should be alkaline as well as saline, and many physicians and surgeons

are adopting his views. He never recommended his solution for subcutaneous use, as he explicitly states. His formula and its advantages were given in *THE JOURNAL* of June 7, p. 1545.—Ed.]

54. Prevention of Snoring.—A small cap fits over the chin and is held in place by a band around the head, fastened to the chin cap with elastic rubber bands. This allows perfect freedom to the lower jaw while at the same time it prevents its dropping down after the subject is asleep, and thus prevents snoring.

55. Diagnosis of Neurasthenia.—Kraepelin emphasizes the harm done by the indiscriminate diagnosis of neurasthenia in various nervous affections. The principal ones confounded with it are progressive paralysis, dementia precox, maniaco-depressive or circular insanity, and the neuroses due to fright, worry, fatigue, the phobias, etc. He describes various points useful in differentiating, and points out that treatment suitable for neurasthenia is directly injurious in some of these other nervous affections. In case of a phobia, for instance, rest and abundant feeding aggravate the trouble. The mild forms of maniaco-depressive or circular insanity are peculiarly liable to simulate neurasthenia, but the alternations with periods of high spirits, the rapid development of the symptoms, the emotional depression, the lack of will power and especially the weariness of life are striking in these cases. Differentiation is important, as suicide is more liable than in genuine neurasthenia, and must be guarded against.

57. Relations Between Bladder Affections and Myomata.—Hahn considers the voluntary retention of urine for hours at a time, common among women, as one of the most prolific causes of bladder troubles later. Another important cause is the displacement of the uterus, and tumors in it, especially myomata. Antelexion of a non-movable uterus, especially during the menstrual period, when it is heavier and the nerves of the region are irritated by the hyperemia, may entail severe bladder disturbances. These are exaggerated if there happens to be a myoma in the uterus. An apparently harmless myoma may, therefore, be the source of a chronic bladder affection or by compression on the ureters may cause urinary disturbances, and if the vessels are compressed there may be varicose veins. Varices can frequently be traced to a myoma, not necessarily very large. Removal of the myoma has in his experience cured a number of such cases and delivered the patients at one stroke from their bladder affections, except in those of exceptionally long standing.

58. Post-Operative Retention of Urine.—Taussig refers to the recent discovery that the essential process in the evacuation of the bladder is depression of the sphincter-tonus. He also calls attention to the frequent occurrence of retention of urine for twenty-four to forty-eight hours after operations, and in particular after those on the female pelvic organs. He tabulates the operations of this kind that have been done at the Bettina at Vienna, 282 in all, during 1899-1901. Post-operative retention was noted in 60 for more than three days, and in 43 for more than six. Retention was most frequent by far in operations entailing extensive detaching of the bladder from its surroundings, and removal of a large portion of the parametrium. This does not induce disturbances in the circulation, as is evidenced by the fact that the urine remains clear and without cellular debris until after the almost inevitable cystitis has made its appearance. He is convinced that the trouble is due to disturbance in the innervation of the bladder caused by the extensive mutilations around it. Treatment, therefore, should be addressed to the innervation of the bladder. The cystitis developed usually about the sixth day and occurred, notwithstanding minute precautions. In some cases the bladder infection was evidently derived from the intestines, as no catheter had been used. In treating the retention, intravesical faradization was found effective in some cases. In two cases expectant treatment for thirty hours was followed by spontaneous urination. Possibly the distension of the bladder walls in these cases stimulated the ganglia located in them. In 5 cases the urethra was dilated in the hope to diminish the tonus of the

sphincter by this procedure. It proved successful in 2 but failed in the 3 others. Spontaneous urination almost always followed the getting up of the patients. But this was not possible until such a late date that the cystitis was already established by that time. In treating the cystitis it was found that urotropin had certainly an inhibiting effect on the bacteria, but it ceased on suspension of the drug. In the severer cases the urotropin proved of little benefit and silver salts were the main reliance.

64. New Blood Reagent.—Strzyzowski calls attention to the peculiarly fine crystals obtained with the following combination: 1 c.c. each of glacial acetic acid, water and alcohol, to which three drops of hydrogen iodid (Iodwasserstoffsäure) are added. The mixture must always be freshly made.

68. Time Required for Absorption of Fat Through the Rectum.—Baum describes the results of researches at von Mering's clinic at Halle in regard to the absorption of rectal alimentary injections. Iodipin is a combination of oil of sesamum and iodine. As it is taken up into the blood by absorption it is decomposed by oxidation and the iodine is liberated. Traces of iodine appear in the secretions, the saliva and urine, within a few minutes after ingestion of iodipin by the mouth. When it is administered by the rectum, the iodine does not appear in the secretions until fifteen hours afterward. Absorption by the rectum does not seem to be influenced by rest or exercise or by eating. Two factors alone seem to have a slight influence on it: the addition of 1.6 per cent. sodium chlorid to the emulsion, and reduction of the proportion of fluid. The rate of absorption varies somewhat in individuals, but is not affected by inflammatory processes in the lower intestines. It is possible that the fat is not absorbed below the ileum, and that there is no absorption in the large intestine. Rectal feeding with fats is of little use in cases of debility in which rapid assimilation is necessary.

69. Internal Gelatin Treatment of Hemophilia.—Hesse's case of a boy of 8 whose mother and grandmother had been anemic, but not bleeders, but the father of the latter had been a typical case of hemophilia and died at 38 from hemorrhage from the mouth, the lungs sound. The tendency had evidently been transmitted latent through two female generations as has been observed in other cases. The child was a very severe case of congenital hemophilia. After failure of all other measures, he was given 200 gm. of a 10 per cent. solution of gelatin every day for six months. The gelatin was flavored with fruit juices. The results have been surprisingly favorable, with disappearance of all symptoms.

70. Blue Electric Light in Therapeutics.—Daniloff reports from Minin's service in the military hospital at St. Petersburg, 12 cases of neuralgic or neuritic affections remarkably improved or cured by the application of blue electric light. The blue electric light expels the blood from the part exposed while the white light causes hyperemia. One case was a colonel who had suffered for nine years from rheumatic neuralgia in one shoulder, worse at night. The cure was complete after 9 applications of the blue electric light. It also aborted in twenty minutes attacks of asthma in 2 patients, the light in this case being merely blue light from an ordinary electric light with reflector. (Minin's apparatus was illustrated in *THE JOURNAL*, August 23, p. 432.)

71. Saline Infusion in Mental Diseases.—Saline infusion acts as a tonic, and at the same time stimulates and enhances the effect of other therapeutic measures. It has been found peculiarly beneficial in acute forms of mental diseases at Anton's clinic at Graz, in subcutaneous injection of from 350 to 400 c.c. of a physiologic salt solution or of Schücking's solution of .12 gm. sodium saccharate and 2.4 gm. sodium chlorid in 400 gm. distilled water. It is especially indicated in "exhaustion psychoses," and in those from intoxication or defective metabolism, in acute and collapse delirium, acute dementia, galloping progressive paralysis, amnesia, Korsakoff's psychosis, catatonia, dementia paranoides, the mental disturbances of puberty and the climacterium, and in incipient stages of melan-

cholia, especially the complicated forms. The back is the most convenient point for the injection in such cases.

73. Gonorrhea and Pregnancy.—Fürst announces that a systematic course of treatment with ichthargan will cure sterility and avert the tendency to abortion in gonorrheal women, while thoroughly curing the basal disease. Ichthargan is reliable, free from untoward effects, does not irritate even the endometrium and exerts its bactericidal power in the depths of the mucosa. It causes no disturbance even when used during the course of a pregnancy. Ichthargan (argent. thiohydrocarburosulfonicum) contains 30 per cent. silver. He applies it by rinsing the endometrium with a 5 per cent. solution and then inserts a 5 per cent. ichthargan bougie in the cervix and tampons the vagina with medicated gauze. Similar bougies are inserted in the urethra up to the opening into the bladder. This treatment is repeated every day for two or three weeks, by which time the cure was complete in his 9 cases of sterility or habitual abortion due to gonorrhea.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

A TEXT-BOOK OF PATHOLOGY AND PATHOLOGIC ANATOMY. By Dr. Hans Schmaus, Extraordinary Professor and First Assistant in the Pathological Institute, Munich. Translated from the Sixth German Edition, by Dr. A. E. Thayer, M.D., Instructor in Pathology in the Cornell University Medical College, New York. Edited, with Additions, by James Ewing, M.D., Professor of Pathology in the Cornell University Medical College, New York. Illustrated with 331 Engravings, including 35 Colored Inset Plates. Cloth. Pp. 602. Price, \$4.00. Philadelphia and New York: Lea Brothers & Co. 1902.

DIET AND FOOD, Considered in Relation to Strength and Power of Endurance, Training and Athletics. By Alexander Haig, M.A., M.D. Oxon., F.R.C.P., Physician to the Metropolitan Hospital, and the Royal Hospital for Children and Women. Fourth Edition. With 7 Illustrations. Cloth. Pp. 127. Price, \$1.00 net. Philadelphia: P. Blakiston's Son & Co. 1902.

A MANUAL OF SURGERY FOR STUDENTS AND PRACTITIONERS. By William Rose, M.B., B.S. Lond., F.R.C.S., Professor of Clinical Surgery in King's College, London, and Albert Carless, M.S. Lond., F.R.C.S., Surgeon to King's College Hospital. Fifth Edition. Cloth. Pp. 1213. Price, \$5.00 net. New York: Wm. Wood & Co. 1902.

DEATH AND SUDDEN DEATH. By P. Brouardel, Professor of Medical Jurisprudence, Dean of the Faculty of Medicine, Paris, and F. Lucas Benham, M.D., B.S. (Lond.), M.D. (Adeleide), Member of the Royal College of Physicians of London. Second Edition. Cloth. Pp. 336. Price, \$3.00. New York: Wm. Wood & Co. 1902.

MANUAL OF GYNECOLOGY. By Henry T. Byford, M.D., Professor of Gynecology and Clinical Gynecology in the College of Physicians and Surgeons of Chicago. Third Revised Edition. Containing 363 Illustrations, Many of Which Are Original. Cloth. Pp. 598. Price, \$3.00 net. Philadelphia: P. Blakiston's Son & Co. 1902.

TRANSACTIONS OF THE MEDICAL AND CHIRURGICAL FACULTY OF THE STATE OF MARYLAND. One Hundred and Fourth Annual Session, Held at Baltimore, April, 1902; Also Semi-Annual Session, Held at Elkton, Md., November, 1901. Paper. Pp. 101. Baltimore: The Deutsch Company.

ELECTRO-CHEMICAL ANALYSIS. By Edgar F. Smith, Professor of Chemistry, University of Pennsylvania. Third Edition, Revised and Enlarged. With 39 Illustrations. Cloth. Pp. 204. Price, \$1.50 net. Philadelphia: P. Blakiston's Son & Co. 1902.

The Public Service.

Army Changes.

Changes in station and duties of officers of the Medical Department, U. S. A., ordered from the Adjutant-General's Office, Washington, D. C., from October 18 to 24, inclusive:

Brooks, John D., contract surgeon, U. S. A., now at Ft. Meade, S. D., will report in person to the commanding officer of that post for duty.

Carter, W. Fitzhugh, major and surgeon, U. S. A. The leave of absence granted Major W. Fitzhugh Carter in Special Orders No. 211, Sept. 8, 1902, from this office, is extended two days.

DeLapre, Samuel M., first lieutenant and asst.-surgeon, U. S. A., recently appointed, now in this city, will report in person at 9 o'clock a. m., on Nov. 6, 1902, at the Army Medical Museum Building, to Colonel Calvin DeWitt, assistant surgeon-general, U. S. A., president of the faculty of the Army Medical School, for the course of instruction prescribed by Paragraphs 542 and 543, Army Regulations.

Fletcher, Richard M., contract surgeon, U. S. A., is relieved from duty at Ft. Meade, S. D., and will proceed to Ft. Niobrara, Neb., and report in person to the commanding officer of the latter post for duty, and by letter to the commanding general, Department of the Missouri.

Fraser, Simon J., major and surgeon, U. S. Vols., now at the Presidio of San Francisco, will proceed to Ft. Bayard, N. M., and re-

port in person to the commanding officer of the U. S. General Hospital at that post for treatment as a patient in that hospital.

Gorgas, William C., major and surgeon, U. S. A., is detailed to represent the Medical Department of the Army at the First Egyptian Medical Congress, to be convened at Cairo, Egypt, in December, 1902, and will proceed at the proper time to that place, via London, England. On the adjournment of the Congress, Major Gorgas will return via London, to this city.

By direction of the Secretary of War the following changes in the stations and duties of officers of the Medical Department are ordered:

Girard, Joseph B., colonel and assistant surgeon-general, U. S. A., on his arrival at San Francisco, will proceed to Omaha, Neb., and report in person to the commanding general, Department of Missouri, for duty as chief surgeon of that department.

Harvard, Valery, lieutenant-col. and deputy surgeon-general, U. S. A., is relieved from duty at Ft. Monroe, Va., and will proceed to West Point, N. Y., and report in person to the superintendent of the U. S. Military Academy for duty, to relieve Major James D. Glennan, surgeon, U. S. A.

Major Glennan, upon being thus relieved, will proceed to Ft. Myer, Va., and report in person to the commanding officer of that post for duty, and by letter to the commanding general, Department of the East, to relieve Major William B. Davis, surgeon, U. S. A.

Major Davis, on being thus relieved, will proceed to Honolulu, Hawaiian Islands, and report in person to the commanding officer of Camp McKinley for duty at that post and by letter to the commanding general, Department of California, to relieve First Lieutenant Edwin W. Rich, asst.-surgeon, U. S. A.

Lieutenant Rich, on being thus relieved, will proceed to San Francisco, and report by telegraph to the Adjutant-General of the Army for orders.

Johnson, Richard W., major and surgeon, U. S. A., is relieved from further duty as sanitary inspector, Department of California, and from duty in San Francisco, and will proceed to Ft. Monroe, Va., and report in person to the commanding officer of that post for duty and by letter to the commanding general, Department of the East.

Wales, Philip G., captain and asst.-surgeon, is relieved from further duty as attending surgeon and examiner of recruits at Denver, Colo., and will proceed to Ft. Assiniboine, Montana, and report in person to the commanding officer of that post for temporary duty and by letter to the commanding general, Department of Dakota.

Overton, David W., contract surgeon, U. S. A., is relieved from duty at Plattsburgh Barracks, N. Y., and will proceed to Ft. Schuyler, N. Y., and report in person to the commanding officer of that post for duty and by letter to the commanding general, Department of the East, to relieve First Lieutenant Theodore C. Lyster, asst.-surgeon, U. S. A.

Lieutenant Lyster, on being thus relieved, will proceed to New York City, for temporary duty as attending surgeon and examiner of recruits in that city, to relieve Captain James S. Wilson, asst.-surgeon, U. S. A.

Captain Wilson, on being thus relieved, will proceed to Ft. Myer, Va., and report in person to the commanding officer of that post for duty and by letter to the commanding general, Department of the East.

Raymond, Thomas U., major and surgeon, U. S. A., is relieved from further duty as attending surgeon and examiner of recruits at Chicago, and will proceed to Jefferson Barracks, Missouri, and report in person to the commanding officer of that post for duty, and by letter to the commanding general, Department of the Missouri, to relieve Captain Francis A. Winter, asst.-surgeon, U. S. A.

Captain Winter, on being thus relieved, will proceed to St. Louis, Mo., and assume the duties of attending surgeon and examiner of recruits in that city.

Childester, Walter C., first lieutenant and asst.-surgeon, U. S. A., now at San Francisco, is relieved from further duty in the Division of the Philippines, and will report in person to the commanding general, Department of California, for assignment to temporary duty in that department.

Sturtevant, Charles A., contract surgeon, is relieved from further duty at Madison Barracks, N. Y., and will proceed to Ft. Totten, N. Y., and report in person to the commanding officer of that post for duty, to relieve First Lieutenant William N. Bispham, asst.-surgeon, U. S. A.

Lieutenant Bispham, on being thus relieved, will proceed to Ft. McHenry, Md., and report in person to the commanding officer of that post for duty.

Ford, Clyde S., first lieutenant and asst.-surgeon, U. S. A., is relieved from further duty at Ft. Hancock, N. J., and will proceed to Ft. Wadsworth, N. Y., and report in person to the commanding officer of the latter post for duty.

Usher, Francis M., first lieutenant and asst.-surgeon, U. S. A., is relieved from further duty at the U. S. General Hospital, San Francisco, and will proceed to Ft. Yellowstone, Wyo., and report in person to the commanding officer of that post for duty, relieving Major Edgar A. Mearns, surgeon, U. S. A.

Major Mearns, on being thus relieved, will proceed to Ft. Snelling, Minn., and report in person to the commanding officer of that post for duty.

Beatty, Walter K., contract surgeon, U. S. A., is relieved from further duty at the U. S. General Hospital, San Francisco, and will report to this city and report by letter to the Surgeon General for annulment of contract.

The leave of absence granted Captain Wm. B. Orear, asst.-surgeon, U. S. Vols., in Special Orders No. 209, Sept. 18, 1902, Department of California, is extended to include Nov. 18, 1902.

Poëy, Eduardo C., captain and asst.-surgeon, U. S. Vols., is honorably discharged by the Secretary of War from the service of the U. S., to take effect Nov. 25, 1902, his services being no longer required.

Robbins, Chandler P., first lieutenant and asst.-surgeon, U. S. A., is granted leave of absence for one month.

Show, Henry A., captain and asst.-surgeon, U. S. A., on arrival at San Francisco, will report to this city and report in person to the commanding officer of the U. S. General Hospital, Washington Barracks, for duty.

Stewart, Wm. J. S., captain and asst.-surgeon, U. S. Vols., now at San Francisco, is honorably discharged by the Secretary of War

from the service of the U. S., to take effect Oct. 22, 1902; his services being no longer required.

Clossman, August von, contract surgeon, U. S. A., is relieved from further duty at Jefferson Barracks, Missouri, and will proceed to his home, St. Louis, Mo., and on arrival report by letter to the Surgeon General of the Army for annulment of contract.

Wilcox, Charles, major and surgeon, U. S. A., is relieved from further duty in the Division of the Philippines and will proceed to San Francisco, and on arrival report by telegraph to the Adjutant-General of the Army for orders.

By direction of the Secretary of War the following-named asst.-surgeons, U. S. A., are relieved from duty at the posts designated after their respective names, to take effect at such times as will enable them to repair to this city and report in person at 9 o'clock a. m., Nov. 6, 1902, at the Army Medical Museum Building, to Col. Calvin DeWitt, assistant surgeon-general, U. S. A., president of the faculty of the Army Medical School, for the course of instruction prescribed by Paragraphs 542 and 543, Army Regulations, 1901.

Gilchrist, Harry L., first lieutenant, Vancouver Barracks, Washington.
Gosman, Geo. H. R., first lieutenant, Ft. Wadsworth, N. Y.
Kirby-Smith, Reynold M., first lieutenant, Ft. Barrancas, Fla.
Moncrief, Wm. H., first lieutenant, Ft. Getty, S. C.
Collins, Geo. L., first lieutenant, Ft. Warren, Mass.
Gapen, Nelson, first lieutenant, Ft. Myer, Va.
Davis, Wm. T., first lieutenant, Ft. McHenry, Md.
Morse, Chas. F., first lieutenant, Ft. Ethan Allen, Vt.
Lambert, Samuel E., first lieutenant, Washington Barracks, D. C.
Hansell, Hayward S., first lieutenant, Ft. McPherson, Ga.
Gregory, Junius C., first lieutenant, Ft. Myer, Va.
Connor, Clarence H., first lieutenant, U. S. General Hospital, Washington Barracks, D. C.

Pyles, Will L., first lieutenant, Plattsburgh Barracks, N. Y.
Devereux, Thomas, first lieutenant, Ft. Snelling, Minn.
Smart, Wm. M., first lieutenant, Ft. Monroe, Va.
Piereson, Robert H., first lieutenant, Ft. Columbus, N. Y.
Snoddy, Cary A., first lieutenant, Ft. Thomas, Ky.
Purnell, Harry S., first lieutenant, Columbus Barracks, Ohio.
Blanchard, Robert M., first lieutenant, Columbus Barracks, Ohio.
Bourke, James, first lieutenant, U. S. General Hospital, San Francisco.
By direction of the Secretary of War a board of medical officers, to consist of Major Louis Brechemin, surgeon, U. S. A.; Major Edward R. Morris, surgeon, U. S. A.; Major Alfred E. Bradley, surgeon, U. S. A.; Captain Henry R. Stiles, asst.-surgeon, U. S. A.; Captain Harry M. Hallock, asst.-surgeon, U. S. A., is appointed to meet in Manila, P. I., as soon as practicable, for the examination of candidates for admission to the Medical Corps of the Army.

Navy Changes.

Changes in the Medical Corps of the Navy, week of Oct. 25, 1902:
Surgeon E. H. Marsteller, ordered to Newark, N. J., October 27, for duty in connection with recruiting.

P. A. Surgeon W. L. Bell, commissioned passed assistant surgeon, with rank of lieutenant (junior grade), from Nov. 16, 1901.

P. A. Surgeon M. W. Garton, detached from the *Columbia* and ordered to the Naval Hospital, Yokohama, Japan, sailing from San Francisco, November 7.

P. A. Surgeon M. K. Johnson, ordered to the Naval Academy.
Asst.-Surgeon J. S. Taylor, detached from the Naval Hospital, Yokohama, Japan, and ordered home and to wait orders.

Asst.-Surgeon R. A. Bachmann, detached from the Naval Academy and ordered to the Naval Museum of Hygiene and Medical School, Washington, D. C., October 31.

Asst.-Surgeon J. H. Holloway, detached from the Naval Hospital, Chelsea, Mass., and ordered to duty at the Museum of Hygiene and Medical School, Washington, D. C.

Asst.-Surgeon R. E. Hoyt, detached from the Naval Academy, and ordered to the Museum of Hygiene and Medical School, Washington, D. C., October 31.

Asst.-Surgeons R. H. Michels, J. L. Nelson, ordered to the Museum of Hygiene and Medical School, Washington, D. C., October 31.

A. A. Surgeons H. Shaw, B. F. Jenness, ordered to the Museum of Hygiene and Medical School, Washington, D. C., October 31.

Orders issued by Commander-in-Chief of Asiatic Station:

Surgeon J. E. Gardner, detached from the Naval Hospital, Yokohama, Japan, and ordered to the *Kentucky*.

Surgeon G. P. Lumsden, ordered to the *New York*.

P. A. Surgeon M. S. Elliott, detached from the *Kentucky* and ordered to the *New York*.

Asst.-Surgeon F. A. Asserson, detached from the *New York* and ordered to the *Kentucky*.

Asst.-Surgeon W. E. High, detached from the *Glacier* and ordered home.

Asst.-Surgeon J. F. Murphy, detached from the Naval Station, Cavite, P. I., and ordered home.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the seven days ended Oct. 23, 1902:

Surgeon C. R. Banks, granted one day's extension of leave of absence, October 11.

P. A. Surgeon J. H. Onkley, granted leave of absence for one day.

P. A. Surgeon H. S. Mathewson, on being relieved by Asst.-Surgeon W. W. King, to proceed to Detroit, Mich., and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon W. W. King, on being relieved by Asst.-Surgeon Jos. Goldberger, to proceed to San Juan, Porto Rico, relieving P. A. Surgeon H. S. Mathewson and assume the duties of chief quarantine officer of the Island of Porto Rico.

Asst.-Surgeon Joseph Goldberger, relieved from duty at Tampico, Mexico, and directed to proceed to Ponce, Porto Rico, relieving Asst.-Surgeon W. W. King and assume command of the service at that port.

A. A. Surgeon S. H. Backus, relieved from duty in the office of the U. S. Consul at Puerto Cortez, Honduras.

A. A. Surgeon W. H. Carson, relieved from duty in the office of the U. S. Consul at Port Limon, Costa Rica.

A. A. Surgeon John Frick, to proceed to Matanzas, Cuba, and assume temporary charge of the service at that port during the absence, on leave, of Asst.-Surgeon R. H. von Ezdorf.

A. A. Surgeon D. W. Goodman, relieved from duty in the office of the U. S. Consul at Bluefields, Nicaragua.

A. A. Surgeon Paul Osterhout, relieved from duty in the office of the U. S. Consul at Bocas del Toro, Colombia.

A. A. Surgeon R. H. Peters, relieved from duty in the office of the U. S. Consul at Belize, British Honduras.

A. A. Surgeon W. B. Robertson, relieved from duty in the office of the U. S. Consul at Celba, Honduras.

Senior Pharmacist and Chemist W. F. Macdowell, to report at Bureau for temporary duty.

BOARD CONVENED.

Board convened at Washington, D. C., October 23, for the physical examination of cadets recently appointed in the Revenue Cutter Service. Detail for the Board. Assistant Surgeon-General W. J. Pettus, chairman; Asst.-Surgeon B. S. Warren, recorder.

PROMOTION.

P. A. Surgeon J. B. Stoner promoted to be surgeon, and to rank as such from September 16.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Oct. 25, 1902:

SMALLPOX—UNITED STATES.

California: Sacramento, Oct. 11-18, 3 cases; San Francisco, Oct. 5-12, 6 cases.

Illinois: Oct. 11-18, Chicago, 3 cases; Freeport, 12 cases.

Indiana: South Bend, Oct. 11-18, 2 cases.

Kentucky: Covington, Oct. 4-18, 21 cases.

Massachusetts: Boston, Oct. 11-18, 6 cases, 3 deaths; Cambridge, Sept. 13-Oct. 4, 1 case, 1 death; Everett, Oct. 11-18, 1 case; Malden, Oct. 11-18, 2 cases.

Michigan: Detroit, Oct. 11-18, 13 cases.

Missouri: St. Louis, Oct. 12-19, 5 cases.

New Hampshire: Nashua, Oct. 11-18, 25 cases.

New Jersey: Newark, Oct. 4-18, 3 cases.

New York: New York, Oct. 11-18, 2 cases.

Ohio: Cincinnati, Oct. 10-17, 2 cases; Cleveland, Oct. 11-18, 34 cases, 5 deaths; Dayton, Oct. 11-18, 1 case; Hamilton, Oct. 11-18, 2 cases.

Pennsylvania: Altoona, Oct. 11-18, 1 case; Erie, Oct. 11-18, 2 cases; Johnstown, Oct. 11-18, 13 cases, 1 death; McKeesport, Oct. 11-18, 1 case; Philadelphia, Oct. 11-18, 2 cases; Pittsburg, Oct. 4-18, 37 cases, 5 deaths; Reading, Oct. 6-13, 2 cases.

South Dakota: Sioux Falls, Oct. 11-18, 1 case.

Utah: Salt Lake City, Sept. 27-Oct. 4, 2 cases.

Washington: Tacoma, Oct. 5-12, 1 case.

Wisconsin: Milwaukee, Oct. 11-18, 22 cases.

SMALLPOX—FOREIGN.

Brazil: Pernambuco, Aug. 15-31, 9 deaths; Rio de Janeiro, Sept. 21-28, 18 deaths.

Canada: Amherstburg, Oct. 11-18, 2 cases.

China: Hongkong, Sept. 6-13, 1 death.

Ecuador: Guayaquil, Sept. 27-Oct. 4, 2 deaths.

France: Marseilles, Sept. 1-30, 18 deaths.

Great Britain: Leeds, Oct. 4-11, 1 case; London, Sept. 27-Oct. 4, 4 cases.

India: Bombay, Sept. 16-23, 5 deaths; Calcutta, Sept. 13-20, 2 deaths.

Italy: Palermo, Sept. 20-27, 8 cases, 1 death.

Russia: Moscow, Sept. 20-27, 2 cases, 1 death; Odessa, Sept. 27-Oct. 4, 1 case.

YELLOW FEVER.

Brazil: Rio de Janeiro, Sept. 21-28, 6 deaths.

Colombia: Panama, Oct. 6-13, 8 cases.

Costa Rica: Port Limon, Oct. 2-9, 3 cases.

Ecuador: Guayaquil, Sept. 27-Oct. 4, 2 deaths.

Mexico: Coatzacoalcas, Oct. 4-11, 3 cases, 1 death; Vera Cruz, Oct. 11-18, 20 cases, 4 deaths.

CHOLERA—INSULAR.

Philippine Islands: To Sept. 13, Manila, 3,974 cases, 2,994 deaths; Provinces, 54,173 cases, 37,713 deaths.

CHOLERA—FOREIGN.

Arabic: Hodeidah, Sept. 10-12, 9 deaths.

China: Hongkong, Sept. 6-13, 1 case, 1 death.

Egypt: Sept. 6-20, 7,235 cases, 13,763 deaths; Alexandria, Sept. 13-20, 82 cases, 208 deaths; Cairo, Sept. 13-20, 28 cases, 102 deaths; Damietta, Sept. 13-20, 52 cases, 182 deaths; Ismailia, Sept. 13-20, 5 cases, 8 deaths; Port Said, Sept. 13-20, 2 cases, 8 deaths; Suez, Sept. 13-20, 31 cases, 41 deaths.

India: Calcutta, Sept. 13-20, 12 deaths; Madras, Aug. 23-Sept. 12, 1 death.

Japan: Fukuoka Ken, to Sept. 22, 1,042 cases, 646 deaths; Hiroshima Ken, to Sept. 22, 706 cases; Kagawa Ken, to Sept. 22, 2,344 cases; Nagasaki, Sept. 11-20, 52 cases, 34 deaths; Okayama Ken, Sept. 11-20, 2,140 cases, 1,455 deaths; Osaka, Sept. 20-27, 45 cases, 28 deaths.

PLAGUE—INSULAR.

Hawaii: Honolulu, Oct. 14, 1 case.

PLAGUE—FOREIGN.

Africa: To Aug. 9, Cape Peninsula, 745 cases, 362 deaths; Port Elizabeth, 135 cases, 66 deaths; Mossel Bay, 13 cases, 4 deaths; other places, 14 cases, 6 deaths.

Australia: New Castle, Aug. 1-31, 1 case, 1 death.

Brazil: Rio de Janeiro, Sept. 21-28, 11 deaths.

China: Hongkong, Sept. 6-13, 1 case, 1 death.

India: Bombay, Sept. 16-23, 55 deaths; Calcutta, Sept. 13-20, 8 deaths; Karachi, Sept. 14-21, 22 cases, 14 deaths; Madras, Aug. 23-Sept. 12, 1 death.

Russia: Odessa, from June to Oct. 4, 43 cases, 14 deaths.

No. 20.

Address.

WILLIAM BEAUMONT.

A PIONEER AMERICAN PHYSIOLOGIST.*

WILLIAM OSLER, M.D.

PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY.
BALTIMORE.

Come with me for a few moments on a lovely June day in 1822, to what were then far-off northern wilds, to the Island of Michilimacinac, where the waters of Lake Michigan and Lake Huron unite and where stands Fort Mackinac, rich in the memories of Indian and voyageur, one of the four important posts on the upper lakes in the days when the rose and the fleur-de-llys strove for the mastery of the western world. Here the noble Marquette labored for his Lord, and here beneath the chapel of St. Ignace they laid his bones to rest. Here the intrepid LaSalle, the brave Tonty and the resolute Du Luht had halted in their wild wanderings. Its palisades and block-houses had echoed the war-whoops of Ojibwas and Ottawas, of Hurons and Iroquois, and the old fort had been the scene of bloody massacres and hard-fought fights, but at the conclusion of the War of 1812, after two centuries of struggle, peace settled at last on the island. The fort was occupied by United States troops, who kept the Indians in check and did general police duty on the frontier, and the place had become a rendezvous for Indians and voyageurs in the employ of the American Fur Company. On this bright spring morning the village presented an animated scene. The annual return tide to the trading post was in full course, and the beach was thronged with canoes and batteaux laden with the pelts of the winter's hunt. Voyageurs and Indians, men, women and children, with here and there a few soldiers, made up a motley crowd. Suddenly from the company's store there is a loud report of a gun, and amid the confusion and excitement the rumor spreads of an accident, and there is a hurrying of messengers to the barracks for a doctor. In a few minutes (Beaumont says twenty-five or thirty, an eye-witness says three) an alert-looking man in the uniform of a U. S. Army surgeon made his way through the crowd and was at the side of a young French Canadian who had been wounded by the discharge of a gun, and with a composure bred of an exceptional experience of such injuries, prepared to make the examination. Though youthful in appearance, Surgeon Beaumont had seen much service, and at the capture of York and at the investment of Plattsburgh he had shown a coolness and bravery under fire which had won high praise from his superior officers. The man and the opportunity had met—the outcome is my story of this evening.

I. THE OPPORTUNITY—ALEXIS ST. MARTIN.

On the morning of June 6 a young French Canadian, Alexis St. Martin, was standing in the company's store, "where one of the party was holding a shotgun (not a musket), which was accidentally discharged, the whole charge entering St. Martin's body. The muzzle was not over three feet from him—I think not more than two. The wadding entered, as well as pieces of his clothing; his shirt took fire; he fell, as we supposed, dead."

"Doctor Beaumont, the surgeon of the fort, was immediately sent for and reached the wounded man in a very short time, probably three minutes. We had just gotten him on a cot and were taking off some of his clothing. After the doctor had extracted part of the shot, together with pieces of clothing, and dressed his wound carefully, Robert Stuart and others assisting, he left him, remarking: 'The man can not live thirty-six hours; I will come and see him by and by.' In two or three hours he visited him again, expressing surprise at finding him doing better than he had anticipated. The next day, after getting out more shot and clothing and cutting off ragged edges of the wound, he informed Mr. Stuart, in my presence, that he thought he would recover."*

The description of the wound has been so often quoted as reported in Beaumont's work that I give here the interesting summary which I find in a "Memorial" presented to the Senate and House of Representatives by Beaumont. "The wound was received just under the left breast, and supposed, at the time, to have been mortal. A large portion of the side was blown off, the ribs fractured and openings made into the cavities of the chest and abdomen, through which protruded portions of the lungs and stomach, much lacerated and burnt, exhibiting altogether an appalling and hopeless case. The diaphragm was lacerated and a perforation made directly into the cavity of the stomach, through which food was escaping at the time your memorialist was called to his relief. His life was at first wholly despaired of, but he very unexpectedly survived the immediate effects of the wound, and necessarily continued a long time under the constant professional care and treatment of your memorialist, and, by the blessing of God, finally recovered his health and strength.

"At the end of about ten months the wound was partially healed, but he was still an object altogether miserable and helpless. In this situation he was declared 'a common pauper' by the civil authorities of the county, and it was resolved by them that they were not able, nor required, to provide for or support, and finally declined

* Statement of G. G. Hubbard, an officer of the company, who was present when St. Martin was shot, quoted by Dr. J. R. Bally, of Mackinac Island, in his address on the occasion of the Beaumont Memorial Exercises, Mackinac Island, July 10, 1900. The Physician and Surgeon, December, 1900.

* An Address before the St. Louis Medical Society, Oct. 4, 1902.

taking care of him, and, in pursuance of what they probably believed to be their public duty, authorized by the laws of the territory, were about to transport him, in this condition, to the place of his nativity in lower Canada, a distance of more than fifteen hundred miles.

"Believing the life of St. Martin must inevitably be sacrificed if such attempt to remove him should be carried into execution at that time, your memorialist, after earnest, repeated, but unavailing, remonstrances against such a course of proceedings, resolved, as the only way to rescue St. Martin from impending misery and death, to arrest the process or transportation and prevent the consequent suffering, by taking him into his own private family, where all the care and attention were bestowed that his condition required.

"St. Martin was, at this time, as before intimated, altogether helpless and suffering under the debilitating effects of his wounds—naked and destitute of everything. In this situation your memorialist received, kept, nursed, medically and surgically treated and sustained him, at much inconvenience and expense, for nearly two years, dressing his wounds daily, and for considerable part of the time twice a day, nursed him, fed him, clothed him, lodged him and furnished him with such necessities and comforts as his condition and suffering required.

"At the end of these two years he had become able to walk and help himself a little, though unable to provide for his own necessities. In this situation your memorialist retained St. Martin in his family for the special purpose of making physiological experiments."

In the month of May, 1825, Beaumont began the experiments. In June he was ordered to Fort Niagara, where, taking the man with him, he continued the experiments until August. He then took him to Burlington and to Plattsburgh. From the latter place St. Martin returned to Canada, without obtaining Dr. Beaumont's consent. He remained in Canada four years, worked as a voyageur, married and had two children. In 1829 Beaumont succeeded in getting track of St. Martin, and the American Fur Company engaged him and transported him to Fort Crawford on the upper Mississippi. The side and wound were in the same condition as in 1825. Experiments were continued uninterruptedly until March, 1831, when circumstances made it expedient that he should return with his family to lower Canada. The "circumstances," as we gather from letters, were the discontent and homesickness of his wife. As illustrating the mode of travel, Beaumont states that St. Martin took his family in an open canoe "via the Mississippi, passing by St. Louis, ascended the Ohio river, then crossed the state of Ohio to the lakes, and descended the Erie and Ontario and the river St. Lawrence to Montreal, where they arrived in June." Dr. Beaumont often lays stress on the physical vigor of St. Martin as showing how completely he had recovered from the wound. In November, 1832, he again engaged himself to submit to another series of experiments in Plattsburgh and Washington. The last recorded experiment is in November, 1833.

Among the Beaumont papers, for an examination of which I am much indebted to his daughter, Mrs. Kein (Appendix A), there is a large mass of correspondence relating to St. Martin, extending from 1827, two years after he had left the doctor's employ, to October, 1852. Alexis was in Dr. Beaumont's employ in the periods already specified. In 1833 he was enrolled in the United States Army at Washington as Sergeant Alexis St. Martin, of a detachment of orderlies stationed at the

War Department. He was then 28 years of age, and was five feet five inches in height.

Among the papers there are two articles of agreement, both signed by the contracting parties, one dated Oct. 19, 1833, and the other November 7 of the same year. In the former he bound himself for a term of one year to "serve, abide and continue with the said William Beaumont, wherever he shall go or travel or reside in any part of the world his covenant servant and diligently and faithfully, etc., . . . that he, the said Alexis, will at all times during said term when thereto directed or required by said William, submit to assist and promote by all means in his power such philosophical or medical experiments as the said William shall direct or cause to be made on or in the stomach of him, the said Alexis, either through and by means of the aperture or opening thereto in the side of him, the said Alexis, or otherwise, and will obey, suffer and comply with all reasonable and proper orders of or experiments of the said William in relation thereto and in relation to the exhibiting and showing of his said stomach and the powers and properties thereto and of the appurtenances and the powers, properties and situation and state of the contents thereof." The agreement was that he should be paid his board and lodging and \$150 for the year. In the other agreement it is for two years and the remuneration \$400. He was paid a certain amount of the money down.

There are some letters from Alexis himself, all written for him and signed with his mark. In June, 1834, he writes that his wife was not willing to let him go and thinks that he can do a great deal better to stay at home. From this time on Alexis was never again in Dr. Beaumont's employ.

There is a most interesting and protracted correspondence in the years 1836, 1837, 1838, 1839, 1840, 1842, 1846, 1851 and 1852, all relating to attempts to induce Alexis to come to St. Louis. For the greater part of this time he was in Berthier, in the district of Montreal, and the correspondence was chiefly conducted with a Mr. William Morrison, who had been in the northwest fur trade and who took the greatest interest in Alexis and tried to induce him to go to St. Louis. (See Appendix B.)

In 1846 Beaumont sent his son Israel for Alexis. and in a letter dated Aug. 9, 1846, his son writes from Troy: "I have just returned from Montreal, but without Alexis. Upon arriving at Berthier I found that he owned and lived on a farm about fifteen miles southwest of the village." Nothing would induce him to go.

The correspondence with Mr. Morrison in 1851 and 1852 is most voluminous, and Dr. Beaumont offered Alexis \$500 for the year, with comfortable support for his family. He agreed at one time to go, but it was too late in the winter and he could not get away.

The last letter of the series is dated Oct. 15, 1852, and is from Dr. Beaumont to Alexis, whom he addresses as *Mon Ami*. Two sentences in this are worth quoting: "Without reference to past efforts and disappointments—or expectation of ever obtaining your services again for the purpose of experiments, etc., upon the proposals and conditions heretofore made and suggested, I now proffer to you in faith and sincerity, new, and I hope satisfactory, terms and conditions to ensure your prompt and faithful compliance with my most fervent desire to have you again with me—not only for my own individual gratification, and the benefits of medical science, but also for your own and family's present good and

future welfare." He concludes with, "I can say no more, Alexis—you know what I *have* done for you many years since—what I have been *trying*, and am still anxious and wishing to do with and for you—what efforts, anxieties, anticipations and disappointments I have suffered from your non-fulfilment of my expectations. Don't disappoint me more nor forfeit the bounties and blessings reserved for you."

So much interest was excited by the report of the experiments that it was suggested to Beaumont that he should take Alexis to Europe and submit him there to a more extended series of observations by skilled physiologists. Writing June 10, 1833, he says: "I shall engage him for five or six years if he will agree, of which I expect there is no doubt. He has always been pleased with the idea of going to France. I feel much gratified at the expression of Mr. Livingston's desire that we should visit Paris, and shall duly consider the interest he takes in the subject and make the best arrangements I can to meet his views and yours." Mr. Livingston, the American minister, wrote from Paris March 18, 1834, saying that he had submitted the work to Orfila and the Academy of Sciences, which had appointed a committee to determine if additional experiments were necessary and whether it was advisable to send to America for Alexis. Nothing, I believe, ever came of this, nor, so far as I can find, did Alexis visit Paris. Other attempts were made to secure him for purposes of study. In 1840 a student of Dr. Beaumont's, George Johnson, then at the University of Pennsylvania, wrote saying that Dr. Jackson had told him of efforts made to get Alexis to London, and Dr. Gibson informed him that the Medical Society of London had raised £300 or £400 to induce St. Martin to come, and that he, Dr. Gibson, had been trying to find St. Martin for his London friends. There are letters in the same year from Dr. R. D. Thomson of London to Professor Silliman urging him to arrange that Dr. Beaumont and Alexis should visit London. In 1856 St. Martin was under the observation of Dr. Francis Gurney Smith, in Philadelphia, who reported a brief series of experiments, so far as I know the only other report made on him.*

St. Martin had to stand a good deal of chaffing about the hole in his side. His comrades called him "the man with a lid on his stomach." In his memorial address Mr. C. S. Osborn of Sault Ste. Marie states that Miss Catherwood tells a story of Etienne St. Martin fighting with Charlie Charette because Charlie ridiculed his brother. Etienne stabbed him severely and swore that he would kill the whole brigade if they did not stop deriding his brother's stomach.

At one time St. Martin traveled about exhibiting the wound to physicians, medical students and before medical societies. In a copy of Beaumont's work, formerly belonging to Austin Flint, Jr., and now in the possession of a physician of St. Louis, there is a photograph of Alexis sent to Dr. Flint. There are statements made that he went to Europe, but of such a visit I can find no record.

My interest in St. Martin was of quite the general character of a teacher of physiology, who every session referred to his remarkable wound and showed Beaumont's book with the illustration. In the spring of 1880, while still a resident of Montreal. I saw a notice in the newspapers of his death at St. Thomas. I immediately wrote to a physician and to the parish priest, urging them to secure me the privilege of an autopsy

and offering to pay a fair sum for the stomach, which I agreed to place in the Army Medical Museum in Washington, but without avail. Subsequently, through the kindness of the Hon. Mr. Justice Baby, I obtained the following details of St. Martin's later life, and the picture here given, which was taken the year before his death so as to show the wound, which I here show you. Judge Baby writes to his friend, Prof. D. C. MacCallum of Montreal, as follows: "I have much pleasure to-day in placing in your hands such information about St. Martin as Revd. Mr. Chicoine, Curé of St. Thomas, has just handed over to me. Alexis Bidigan, *dit* St. Martin, died at St. Thomas de Joliette on the 24th of June, 1880, and was buried in the cemetery of the parish on the 28th of the same month. The last sacraments of the

ALEXIS ST. MARTIN, AGED 81.

Catholic church were ministered to him by the Revd. Curé Chicoine, who also attended at his burial service. The body was then in such an advanced stage of decomposition that it could not be admitted into the church, but had to be left outside during the funeral service. The family resisted all requests—most pressing as they were—on the part of the members of the medical profession for an autopsy, and also kept the body at home much longer than usual and during a hot spell of weather, so as to allow decomposition to set in and baffle, as they thought, the doctors of the surrounding country and others. They had also the grave dug eight feet below the surface of the ground in order to prevent any attempt at a resurrection. When he died St. Martin was 83 years of age, and left a widow, whose maiden name was Marie Joly. She survived him by

* Medical Examiner, 1856, and Experiments on Digestion, Phila., 1856

nearly seven years, dying at St. Thomas on the 20th of April, 1887, at the very old age of 90 years. They left four children still alive—Alexis, Charles, Henriette and Marie.

"Now I may add the following details for myself. When I came to know St. Martin it must have been a few years before his death. A law suit brought him to my office here in Joliette. I was seized with his interests; he came to my office a good many times, during which visits he spoke to me at great length of his former life, how his wound had been caused, his peregrinations through Europe and the United States, etc. He showed me his wound. He complained bitterly of some doctors who had awfully misused him, and had kind words for others. He had made considerable money during his tours, but had expended and thrown it all away in a frolicsome way, especially in the old country. When I came across him he was rather poor, living on a small, scanty farm in St. Thomas, and very much addicted to drink, almost a drunkard one might say. He was a tall, lean man, with a very dark complexion, and appeared to me then of a morose disposition."

II. THE BOOK.

In the four periods in which Alexis had been under the care and study of Beaumont a large series of observations had been recorded, amounting in all to 238. A preliminary account of the case and of the first group of observations appeared in the *Philadelphia Medical Recorder* in January, 1825. During the stay in Washington in 1832 the great importance of the observations had become impressed on the Surgeon-General, Dr. Lovell, who seems to have acted in a most generous and kindly spirit. Beaumont tried to induce him to undertake the arrangement of the observations, but Lovell insisted that he should do the work himself. In the spring of 1833 Alexis was taken to New York and there shown to the prominent members of the profession, and careful drawings and colored sketches were made of the wound by Mr. King. A prospectus of the work was issued and was distributed by the Surgeon-General, who speaks in a letter of sending them to Dr. Franklin Bache and to Dr. Stewart of Philadelphia, and in a letter from Dr. Bache to Dr. Beaumont acknowledging the receipt of a bottle of gastric juice, Bache states that he has placed the prospectus in Mr. Judah Dobson's store and has asked for subscribers. Beaumont did not find New York a very congenial place. He complained of the difficulty of doing the work owing to the vexatious social intercourse. He applied for permission to go to Plattsburgh, in order to complete the book. After having made inquiries in New York and Philadelphia about terms of publication he decided, as the work had to be issued at his own expense, that it could be as well and much more cheaply printed at Plattsburgh, where he would also have the advice and help of his cousin, Dr. Samuel Beaumont. In a letter to the Surgeon-General, dated June 10, 1833, he acknowledges the permission to go to Plattsburgh, and says: "I shall make my arrangements to leave here for Pl. in about a week to *rush* the execution of the Book as fast as possible. I am now having the drawings taken by Mr. King engraved here."

The summer was occupied in making a fresh series of experiments and getting the work in type. On December 3 he writes the Surgeon-General that the book will be ready for distribution in a few days and that 1,000 copies will be printed.

The work is an octavo volume of 280 pages, entitled "Experiments and Observations on the Gastric Juice and the Physiology of Digestion," by William Beau-

mont, M.D., Surgeon in the United States Army. Plattsburgh. Printed by F. P. Allen, 1833. While it is well and carefully printed, the paper and type are not of the best, and one can not but regret that Beaumont did not take the advice of Dr. Franklin Bache, who urged him strongly not to have the work printed at Plattsburgh, but in Philadelphia, where it could be done in very much better style. The dedication of the work to Joseph Lovell, M.D., Surgeon-General of the United States Army, acknowledges in somewhat laudatory terms the debt which Beaumont felt he owed to his chief, who very gratefully acknowledges the compliment and the kindly feeling, but characterizes the dedication as "somewhat apocryphal."

The work is divided into two main portions; first, the preliminary observations on the general physiology of digestion in seven sections: Section I, Of Aliment; Section II, Of Hunger and Thirst; Section III, of Satisfaction and Satiety; Section IV, Of Mastication, Insalivation and Deglutition; Section V, Of Digestion by the Gastric Juice; Section VI, Of the Appearance of the Villous Coat, and of the Motions of the Stomach; Section VII, Of Chylification and Uses of the Bile and Pancreatic Juice. The greater part of the book is occupied by the larger section of the detailed account of the four series of experiments and observations. The work concludes with a series of 51 inferences from the foregoing experiments and observations.

The subsequent history of the book itself is of interest, and may be dealt with here. In 1834 copies of the Plattsburgh edition, printed by F. P. Allen, were issued by Lilly, Wait & Co., of Boston.

In the Beaumont correspondence there are many letters from a Dr. McCall, in Utica, N. Y., who was an intimate friend of a Mr. Wm. Combe, a brother of the well-known physiologist and popular writer, Dr. Andrew Combe of Edinburgh. Doubtless it was through this connection that in 1838 Dr. Combe issued an edition in Scotland, with numerous notes and comments. (Appendix C.)

The second edition was issued from Burlington, Vt., in 1847, with the same title page, but after Second Edition there are the words, Corrected by Samuel Beaumont, M.D., who was Dr. William Beaumont's cousin. In the preface to this edition the statement is made that the first edition, though a large one of 3,000 copies, had been exhausted. This does not agree with the statement made in a letter of Dec. 3, 1833, to the Surgeon-General, stating that the edition was to be 1,000 copies. Of course more may have been printed before the type was distributed. While it is stated to be a new and improved edition, so far as I can gather it is a verbatim reprint, with no additional observations, but with a good many minor corrections. In an appendix (D) I give an interesting letter from Dr. Samuel Beaumont with reference to the issue of this edition.

A German edition was issued in 1834 with the following title: "Neue Versuche und Beobachtungen ueber den Magensaft und die Physiologie der Verdauung, auf eine höchst merkwürdige Weise während einer Reihe von 7 Jahren, an einen und demselben Subject angestellt." Beaumont's earlier paper, already referred to, was abstracted in the *Magazin der ausländischen Litteratur der gesammten Heilkunde*, Hamburg. 1826, and also in the *Archives generales de Medecine*, Paris, 1828. I can not find that there was a French edition of the work.

The "Experiments and Observations" attracted universal attention, both at home and abroad. The jour-

nals of the period contained very full accounts of the work, and within a few years the valuable additions to our knowledge filtered into the text-books of physiology, which to-day in certain descriptions of the gastric juice and of the phenomena of digestion even the very language of the work is copied.

III. THE VALUE OF BEAUMONT'S OBSERVATIONS.

There had been other instances of artificial gastric fistula in man which had been made the subject of experimental study, but the case of St. Martin stands out from all others on account of the ability and care with which the experiments were conducted. As Dr. Combe says, the value of these experiments consists partly in the admirable opportunities for observation which Beaumont enjoyed, and partly in the candid and truth-seeking spirit in which all his inquiries seem to have been conducted. "It would be difficult to point out any observer who excels him in devotion to truth and freedom from the trammels of theory or prejudice. He tells plainly what he saw and leaves every one to draw his own inferences, or where he lays down conclusions he does so with a degree of modesty and fairness of which few perhaps in his circumstances would have been capable."

To appreciate the value of Beaumont's studies it is necessary to refer for a few moments to our knowledge of the physiology of digestion in the year 1832, the date of the publication. Take, for example, "The Work on Human Physiology" (published in the very year of the appearance of Beaumont's book), by Dunglison, a man of wide learning and thoroughly informed in the literature of the subject. The five or six old theories of stomach digestion, concoction, putrefaction, trituration, fermentation and maceration, are all discussed, and Wm. Hunter's pithy remark is quoted, "some physiologists will have it, that the stomach is a mill, others, that it is a fermenting vat, others, again, that it is a stew-pan; but, in my view of the matter, it is neither a mill, a fermenting vat nor a stew-pan; but a stomach, gentlemen, a stomach."

The theory of chemical solution is accepted. This had been placed on a sound basis by the experiments of Reaumur, Spallanzani and Stevens, while the studies of Tiedemann and Gmelin and of Prout had done much to solve the problems of the chemistry of the juice. But very much uncertainty existed as to the phenomena occurring during digestion in the stomach, the precise mode of action of the juice, the nature of the juice itself and its action outside the body. On all these points the observations of Beaumont brought clearness and light where there had been previously the greatest obscurity.

The following may be regarded as the most important of the results of Beaumont's observations: First, the accuracy and completeness of description of the gastric juice itself. You will all recognize the following quotation, which has entered into the text-books and passes current to-day. "Pure gastric juice, when taken directly out of the stomach of a healthy adult, unmixed with any other fluid, save a portion of the mucus of the stomach with which it is most commonly and perhaps always combined, is a clear, transparent fluid; inodorous; a little saltish, and very perceptibly acid. Its taste, when applied to the tongue, is similar to this mucilaginous water slightly acidulated with muriatic acid. It is readily diffusible in water, wine or spirits; slightly effervesces with alkalies; and is an effectual solvent of the *materia alimentaria*. It possesses the property of coagulating albumen, in an eminent degree; is powerfully antiseptic, checking the putrefaction

of meat; and effectually restorative of healthy action, when applied to old, foetid sores and foul, ulcerating surfaces."

Secondly, the confirmation of the observation of Prout that the important acid of the gastric juice was the muriatic or hydrochloric. An analysis of St. Martin's gastric juice were made by Dunglison, at that time a professor in the University of Virginia, and by Benjamin Silliman of Yale, both of whom determined the presence of free hydrochloric acid. A specimen was sent to the distinguished Swedish chemist, Berzelius, whose report did not arrive in time to be included in the work. In a letter dated July 19, 1834, he writes to Professor Silliman that he had not been able to make a satisfactory analysis of the juice. The letter is published in *Silliman's Journal*, Vol. 27, July, 1835.

Thirdly, the recognition of the fact that the essential elements of the gastric juice and the mucus were separate secretions.

Fourthly, the establishment by direct observation of the profound influence on the secretion of the gastric juice and on digestion of mental disturbances.

Fifthly, a more accurate and fuller comparative study of the digestion in the stomach with digestion outside the body, confirming in a most elaborate series of experiments the older observations of Spallanzani and Stevens.

Sixthly, the refutation of many erroneous opinions relating to gastric digestion and the establishment of a number of minor points of great importance, such as, for instance, the rapid disappearance of water from the stomach through the pylorus, a point brought out by recent experiments, but insisted on and amply proven by Beaumont.

Seventhly, the first comprehensive and thorough study of the motions of the stomach, observations on which, indeed, are based the most of our present knowledge.

And lastly, a study of the digestibility of different articles of diet in the stomach, which remains to-day one of the most important contributions ever made to practical dietetics.

The greater rapidity with which solid food is digested, the injurious effects on the stomach of tea and coffee, when taken in excess, the pernicious influence of alcoholic drinks on the digestion, are constantly referred to. An all-important practical point insisted on by Beaumont needs emphatic reiteration to this generation: "The system requires much less than is generally supplied to it. The stomach disposes of a definite quantity. If more be taken than the actual wants of the economy require, the residue remains in the stomach and becomes a source of irritation and produces a consequent aberration of function, or passes into the lower bowel in an undigested state, and extends to them its deleterious influence. Dyspepsia is oftener the effect of over-eating and over-drinking than of any other cause."

One is much impressed, too, in going over the experiments, to note with what modesty Beaumont refers to his own work. He speaks of himself as a humble "enquirer after truth and a simple experimenter." "Honest objection, no doubt, are entertained against the doctrine of digestion by the gastric juice. That they are so entertained by these gentlemen I have no doubt. And I cheerfully concede to them the merit of great ingenuity, talents and learning, in raising objections to the commonly received hypothesis, as well as ability in maintaining their peculiar opinions. But we ought

not to allow ourselves to be seduced by the ingenuity of argument or the blandishments of style. Truth, like beauty, when 'unadorned is adorned the most'; and in prosecuting these experiments and inquiries, I believe I have been guided by its light. Facts are more persuasive than arguments, however ingeniously made, and by their eloquence I hope I have been able to plead for the support and maintenance of those doctrines which have had for their advocates such men as Sydenham, Hunter, Spallanzani, Richerand, Abernethy, Broussais, Philip, Paris, Bostock, the Heidelberg and Paris professors, Dunglison, and a host of other luminaries in the science of physiology."

In reality Beaumont anticipated some of the most recent studies in the physiology of digestion. Doubtless many of you have heard of Professor Pawlow's, of St. Petersburg, new work on the subject. It has been translated into German, and I see that an English edition is advertised. He has studied the gastric juice in an isolated pouch, ingeniously made at the fundus of the stomach of the dog, from which the juice could be obtained in a pure state. One of his results is the very first announced by Beaumont and confirmed by scores of observations on St. Martin, viz., that, as he says, "the gastric juice never appears to be accumulated in the cavity of the stomach while fasting." Pawlow has shown very clearly that there is a relation between the amount of food taken and the quantity of gastric juice secreted. Beaumont came to the same conclusion: "when aliment is received the juice is given in exact proportion to its requirements for solution." A third point on which Pawlow lays stress is the curve of secretion of the gastric juice, the manner in which it is poured out during digestion. The greatest secretion, he has shown, takes place in the earlier hours. On this point hear Beaumont: "It (the gastric juice) then begins to exude from the proper vessels and increases in proportion to the quantity of aliment naturally required and received." And again: "When a due and moderate supply of food has been received it is probable that the whole quantity of gastric juice for its complete solution is secreted and mixed with it in a short time." A fourth point, worked out beautifully by Pawlow, is the adaptation of the juice to the nature of the food, on which I do not see any reference by Beaumont, but there are no experiments more full than those in which he deals with the influence of exercise, weather and the emotions on the quantity of the juice secreted.

IV. MAN AND DOCTOR.

Sketches of Dr. Beaumont's life have appeared from time to time. There is a worthy memoir by Dr. T. Reyburn in the *St. Louis Medical and Surgical Journal*, 1854, and Dr. A. J. Steele, at the first annual commencement of the Beaumont Medical College, 1887, told well and graphically the story of his life. A few years ago Dr. Frank J. Lutz, of this city, sketched his life for the memorial meeting of the Michigan State Medical Society on the occasion of the dedication of a Beaumont monument.

Among the papers kindly sent to me by his daughter, Mrs. Keim, are many autobiographical materials, particularly relating to his early studies and to his work as a surgeon in the War of 1812. There is an excellent paper in the handwriting, it is said, of his son, giving a summary of the earlier period of his life. So far as I know this has not been published, and I give it in full:

Dr. William Beaumont was born in the town of Lebanon, Conn., on the 21st day of November, A. D. 1785. His father

was a thriving farmer and an active politician of the proud old Jeffersonian school, whose highest boast was his firm support and strict adherence to the honest principles he advocated. William was his third son, who, in the winter of 1806-7, in the 22d year of his age, prompted by a spirit of independence and adventure, left the paternal roof to seek a fortune and a name. His outfit consisted of a horse and cutter, a barrel of cider, and one hundred dollars of hard-earned money. With this he started, laying his course northwardly, without any particular destination, Honor his rule of action, Truth his only landmark, and trust placed implicitly in Heaven. Traversing the western part of Massachusetts and Vermont in the spring of 1807 he arrived at the little village of Champlain, N. Y., on the Canada frontier—an utter stranger, friendless and alone. But honesty of purpose and true energy invariably work good results. He soon gained the people's confidence and was entrusted with their village school, which he conducted about three years, devoting his leisure hours to the study of medical works from the library of Dr. Seth Pomeroy, his first patron. He then went over to St. Albans, Vt., where he entered the office of Dr. Benjamin Chandler and commenced a regular course of medical reading, which he followed for two years, gaining the utmost

WILLIAM BEAUMONT.

confidence and esteem of his kind preceptor and friends. About this time the War of 1812 commenced, and he applied for an appointment in the U. S. Army, successfully. He was appointed assistant-surgeon to the Sixth Infantry, and joined his regiment at Plattsburgh, N. Y., on the 13th of September, 1812. On the 19th of March, 1813, he marched from Plattsburgh with the First Brigade, for Sackett's Harbor, where they arrived on the 27th inst. Here he remained in camp till the 22d of April, when he embarked with the troops on Lake Ontario. His journal will best tell this portion of his history:

"April 22, 1813.—Embarked with Captain Humphreys, Walworth and Muhlenburg, and companies on board the Schooner 'Julia.' The rest of the brigade, and the Second, with Forsyth's Rifle Regiment and the Eighth Artillery, on board a ship, brig and schooner—remain in the harbor till next morning.

"23d.—11 o'clock a. m.—Weighs anchor and put out under the impression we were going to Kingston. Got out 15 or 20 miles—encountered a storm—wind ahead and the fleet returned to harbor.

"24th.—6 o'clock a. m.—Put out with a fair wind—mild and pleasant—the fleet sailing in fine order.

"26th.—Wind pretty strong—increasing—waves run high, tossing our vessels roughly. At half past four pass the mouth of Niagara river. This circumstance baffles imagination as to

where we are going—first impressed with the idea of Kingston—then to Niagara—but now our destination must be 'Little York.' At sunset came in view of York Town and the Fort, where we lay off some 3 or 4 leagues for the night.

"27th.—Sailed into harbor and came to anchor a little below the British Garrison. Filled the boats and effected a landing, though not without difficulty and the loss of some men. The British marched their troops down the beach to cut us off as landing, and, though they had every advantage, they could not effect their design. A hot engagement ensued, in which the enemy lost nearly a third of their men and were soon compelled to quit the field, leaving their dead and wounded strewn in every direction. They retired to the Garrison, but from the loss sustained in the engagement, the undaunted courage of our men, and the brisk firing from our fleet, with the 12 and 32 pounders, they were soon obliged to evacuate it and retreat with all possible speed.—Driven to this alternative they devised the inhuman project of blowing up their magazine, containing 300 pounds of powder, the explosion of which had well-nigh destroyed our army. Over 300 were wounded and about 60 killed on the spot, by stones of all dimensions falling, like a shower of hail, in the midst of our ranks. A most distressing scene ensues in the hospital. Nothing is heard but the agonizing groans and supplications of the wounded and the dying. The surgeons wade in blood cutting off arms and legs and trepaning heads, while the poor sufferers cry, 'O, my God! Doctor, relieve me from this misery! I can not live!' 'Twas enough to touch the veriest heart of steel and move the most relentless savage. Imagine the shocking scene, where fellow-beings lie mashed and mangled—legs and arms broken and sundered—heads and bodies bruised and mutilated to disfigurement! My deepest sympathies were roused—I cut and slashed for 36 hours without food or sleep.

"29th.—Dressed upwards of 50 patients—from simple contusions to the worst of compound fractures—more than half the latter. Performed two cases of amputation and one of trepanning. At 12 p. m. retired to rest my fatigued body and mind."

One month after the taking of York he witnessed the storming of Fort George. The troops were transported from York to "Four-Mile Creek" (in the vicinity of Ft. George), where they encamped from the 10th of May to the 27th, when they advanced to the attack. His journal runs thus:

"May 27 (1813).—Embarked at break of day—Col. Scott with 800 men, for the advanced guard, supported by the First Brigade, commanded by General Boyd, moved in concert with the shipping to the enemy's shore and landed under their battery and in front of their fire with surprising success, not losing more than 30 men in the engagement, though the enemy's whole force was placed in the most advantageous situation possible. We routed them from their chosen spot—drove them from the country and took possession of the town and garrison."

On the 11th of September, 1814, he was at the Battle of Plattsburgh, still serving as assistant-surgeon, though doing all the duty of a full surgeon. At the close of the war, in 1815, when the Army was cut down, he was retained in service, but resigned soon after, deeming himself unjustly treated by the government in having others, younger and less experienced, promoted over him.

In 1816 he settled in Plattsburgh and remained there four years in successful practice. In the meantime his army friends had persuaded him to join the service again, and, having applied, he was reappointed, in 1820, and ordered to Ft. Mackinac as post surgeon. At the end of the first year he obtained leave of absence, returned to Plattsburgh and married one of the most amiable and interesting ladies of that place. (She still survives her honored husband, and in her green old age is loved devotedly by all who know her.) He returned to Mackinac the same year, and in 1822 came in possession of Alexis St. Martin, the subject of his "Experiments on the Gastric Juice." By the accidental discharge of his gun, while hunting, St. Martin had dangerously wounded himself in the abdomen and came under the treatment of Dr. Beaumont, who healed the wound (in itself a triumph of skill almost unequalled) and in 1825 commenced a series of experiments, the results of which have a world-wide publication. These experi-

ments were continued, with various interruptions, for eight years, during which time he was ordered from post to post—now at Niagara, N. Y., anon as Green Bay, Mich., and finally at Fort Crawford, on the Mississippi. In 1834 he was ordered to St. Louis, where he remained in service till 1839, when he resigned. He then commenced service with the citizens of St. Louis, and from that time till the period of his last illness, enjoyed an extensive and distinguished practice, interrupted only by the base attacks of a few disgraceful and malicious knaves (self-deemed members of the medical profession) who sought to destroy a reputation which they could not share. They gained nothing except some little unenviable notoriety and they have skulked away like famished wolves, to die in their hiding places.

The dates of Beaumont's commissions in the army are as follows: Surgeon's Mate, Sixth Regiment of Infantry, Dec. 2, 1812; Cavalry, March 27, 1819; Post Surgeon, Dec. 4, 1819; Surgeon First Regiment and Surgeon, Nov. 6, 1826.

From the biographical sketches of Reyburn, Steele and Lutz, and from the personal reminiscences of his friends, Drs: J. B. Johnson, S. Pollak and Wm. McPheeters, who fortunately remains with you, full of years and honors, we gather a clearly-defined picture of the latter years of his life. It is that of a faithful, honest, hard-working practitioner, doing his duty to his patients, and working with zeal and ability for the best interests of the profession. The strong common sense which he exhibited in his experimental work made him a good physician and a trustworthy adviser in cases of surgery. Among his letters there are some interesting pictures of his life, particularly in his letters to his cousin, Dr. Samuel Beaumont. Writing to him April 4, 1846, he says:

I have a laborious, lucrative and increasing practice, more than I can possibly attend to, though I have an assistant, Dr. Johnson, a young man who was a pupil of mine from 1835 to 1840. He then went to Philadelphia a year or two to attend lectures, and graduated, and returned here again in 1842, and has been very busy ever since and is so now, but notwithstanding I decline more practice daily than half the doctors in the city get in a week. You thought when you were here before that there was too much competition for you ever to think of succeeding in business here—there is ten times as much now and the better I succeed and prosper for it. You must come with a different feeling from your former—with a determination to follow in my wake and stem the current that I will break for you. I am now in the grand climacteric of life, three-score years and over, with equal or more zeal and ability to do good and contribute to professional service than at forty-five, and I now look forward with pleasing anticipation of success and greater usefulness—have ample competence for ourselves and children, and no doleful or dreaded aspect of the future—to be sure I have to wrestle with some adverse circumstances of life, and more particularly to defend myself against the envious, mean and professional jealousies and the consequent prejudices of some men, but I triumph over them all and go ahead in defiance of them.*

His professional work increased enormously with the rapid growth of the city, but he felt, even in his old age, that delicious exhilaration which it is your pleasure and privilege to enjoy here in the west in a degree rarely experienced by your eastern confrères. Here is a cheery paragraph from a letter dated Oct. 20, 1852: "Domestic affairs are easy, peaceable and pleasant. Health of community good—no severe epidemic diseases prevalent—weather remarkably pleasant—business of all kinds increasing—product of the earth abundant—money plenty—railroads progressing with almost tele-

* He had evidently hoped that when his cousin and son arrived with Alexis they would arrange and plan for another series of experiments and in another year or two make another book, better than the old one.

graphic speed,—I expect to come to Plattsburgh next summer all the way by rail."

But work was becoming more burdensome to a man nearing threescore years and ten, and he expresses it in another letter when he says: "There is an immense professional practice in this city. I get tired of it, and have been trying hard to withdraw from it altogether, but the more I try the tighter I seem to be held to it by the people. I am actually persecuted, worried and almost worn out with valetudinarian importunities and hypochondriacal groans, repinings and lamentations—Amen."

He continued at work until March, 1853, when he had an accident—a fall while descending some steps. A few weeks later a carbuncle appeared on the neck, and proved fatal April 25. One who knew him well wrote the following estimate (quoted by Dr. F. J. Lutz in his sketch of Beaumont):

"He was gifted with strong natural powers, which working upon an extensive experience in life, resulted in a species of natural sagacity, which, as I suppose, was something peculiar in him, and not to be attained by any course of study. His temperament was ardent, but never got the better of his instructed and disciplined judgment, and whenever or however employed, he ever adopted the most judicious means for attaining ends that were always honorable. In the sick room, he was a model of patience and kindness, his intuitive perceptions, guiding a pure benevolence, never failed to inspire confidence, and thus he belonged to that class of physicians whose very presence affords Nature a sensible relief."

You do well, citizens of St. Louis and members of our profession, to cherish the memory of William Beaumont. Alive you honored and rewarded him, and there is no reproach against you of neglected merit and talents unrecognized. The profession of the northern part of the state of Michigan has honored itself in erecting a monument to his memory near the scene of his disinterested labors in the cause of humanity and science. His name is linked with one of your educational institutions, and joined with that of a distinguished laborer in another field of practice. But he has a far higher honor than any you can give him here—the honor that can only come when the man and the opportunity meet—and match. Beaumont is the pioneer physiologist of this country, the first to make an important and enduring contribution to this science. His work remains a model of patient, persevering investigation, experiment and research, and the highest praise we can give him is to say that he lived up to and fulfilled the ideals with which he set out and which he expressed when he said: "Truth, like beauty, when 'unadorned, is adorned the most,' and, in prosecuting these experiments and enquiries, I believe I have been guided by its light."

APPENDIX A.

The Beaumont papers in the possession of his daughter, Mrs. Keim of St. Louis, consist of (1) interesting certificates from his preceptors, Dr. Pomeroy and Dr. Chandler, the license from the Third Medical Society of Vermont, the commissions in the U. S. Army, several certificates of honorary membership in societies, and the parchment of the M.D. degree conferred upon him, *honoris causa*, by the Columbian University of Washington, 1833; (2) a journal containing his experiences in the War of 1812, from which I give an extract, a journal of his trip to Fort Mackinac, a journal containing the reports of many cases, among them that of St. Martin (in addition there is a protocol of the case in loose folio sheets), a journal of the experiments, and a commonplace book of receipts and jottings; (3) an extensive correspondence relating to St. Martin and the

book, and many rough drafts of sections of the book; (4) a large mass of personal correspondence, much of it of interest as relating to conditions of practice in St. Louis.

The picture reproduced here in his army uniform is from a miniature; the picture which has been previously reproduced is of an older man from a daguerreotype. It is satisfactory to know that the ultimate destination of this most valuable collection of papers is the Surgeon-General's Library of the United States Army, of which Dr. Beaumont was so distinguished an ornament.

APPENDIX B.

On Oct. 20, 1853, he writes to his cousin, Dr. Samuel Beaumont, on the subject of "that old, fistulous Alexis," as he calls him. "Alexis' answer to yours is the very fac-simile or stereotype of all his Jesuitical letters to me for the last fifteen years. His object seems only to be to get a heavy bonus and undue advance from me and then disappoint and deceive me, or to palm and impose himself and whole family upon me for support for life.

"I have evaded his designs so far; but I verily fear that the strong and increasing impulse of conscious conviction of the great benefits and important usefulness of further and more accurate physiological investigation of the subject will compel me to still further efforts and sacrifices to obtain him. Physiological authors and most able writers on dietetics and gastric functions generally demand it of me in trumpet tones.

"I must have him at all hazards, and obtain the necessary assistance to my individual and private efforts or transfer him to some competent scientific institution for thorough investigation and report—I must retrieve my past ignorance, imbecility and professional remissness of a quarter of a century, or more, by double diligence, intense study and untiring application of soul and body to the subject before I die—

Should posthumous Time retain my name,
Let historic truths declare my fame.

"Simultaneous with this I write to Mr. Morrison and Alexis my last and final letters—perhaps, proposing to him, as bribe to his cupidity, to give him \$500 to come to me *without* his family, for one year—\$300 of them for his salary, and \$200 for the support and contentment of his family to remain in Canada in the meantime—with the privilege of bringing them on here another year, upon my former proposition of \$300 a year, at his own expense and responsibility and support them himself after they get here out of his \$300 salary—I think he will take the bait and come on this fall, and when I get him alone again into my keeping and engagement, I will take good care to control him as I please."

APPENDIX C.

Letter from Dr. Andrew Combe, May 1, 1838:

"My Dear Sir—May I beg your acceptance of the accompanying volumes as a small expression of my respect for your character and scientific labors. I need not detain you by repeating in this note the high estimation in which I hold you. The volumes herewith sent will, I trust, convince you of the fact, and that it will not be my fault if you do not receive the credit justly due to your valuable and disinterested services. I remain, My Dear Sir, Very respectfully yours,

"ANDW. COMBE."

APPENDIX D.

Letter from Dr. Samuel Beaumont, March 16, 1846:

"Your letter of the 1st of February arrived here in the course of mail, and I have attended to the business which you authorized me to do. I am afraid, however, that you will be disappointed, and perhaps dissatisfied with the arrangement. Mr. Goodrich came here some five or six days after I received your letter, and made his proposal, which was to give you every tenth copy for the privilege of publishing an edition. The number he proposed to publish was fifteen hundred, which would give you 150 copies. I did not like to close the bargain on this condition, and he was not disposed to give any more. This was in the evening. I told him to give me time till the next morning, and I would make up my mind. In the morning, after consultation, I concluded to offer him the copyright for the unexpired time (only one year) for two hundred copies.

After some demurring, we closed the bargain. I then thought and I still think it was not enough; but it was all I could get. In making up my mind the following considerations presented themselves: First, that the copyright would expire in one year, and he would then have the right to print it without consulting the author; second, that it would be somewhat mortifying to the author not to have his work republished, even if no great pecuniary benefit was to be obtained by such a republication; and it appeared to me to be quite certain that a new edition would not be soon printed, if I let this opportunity slip; third, I have been long anxious, as I presume you have been, to see the work gotten up in a better dress than it originally had, and in a way which will give it a general credit and more notoriety among all classes of the reading public than it has heretofore possessed—in fact, make it a standard work; fourth, it has given us a chance to give it a thorough correction, a thing which was very desirable. The work, you recollect, was got up in a great hurry, and a great many errors escaped our notice. You may also recollect that the Philadelphia reviewer spoke of the inaccuracies in the work. And he had reason enough for it. In looking over the work critically with a view of correction, I have been perfectly astonished at the errors that occur on almost every page. And although we understood perfectly what we meant to say, the reader would find it somewhat difficult to decipher our meaning. In the first 140 pages I made nearly 300 corrections. These are practically merely verbal alterations or change of phrases or sentences so as to make them more accurate or perspicuous. I have in no case so changed the text as to give it a different meaning. I flatter myself that it will now be more worthy the public patronage; and if for no other, this chance for correction I consider alone almost a sufficient remuneration for the brief limits of the copyright. I have also written a preface for the second edition, making quotations from American and European authorities in praise of the merits of the work. From delicacy I have written this as from the publisher. I think it is pretty well done. The work will probably be published in the course of about a month, and those designed for you will be delivered to me, when I shall send them to you. He guarantees not to sell in the state of Missouri, or the states south and west of that state. But that, of course, is all gammon. The book will be thrown into market, and he can not control the direction in which it will go."

PNEUMONIA.

ITS FATALITY AND INCREASING PREVALENCE, WITH SUGGESTIONS FOR INDIVIDUAL AND COMMUNAL PROPHYLAXIS.*

EDWARD F. WELLS, M.D.
CHICAGO.

Pneumonia has always attracted the earnest attention of physicians, from the times of Hippocrates and Galen to the present. Under its malign influence many illustrious persons have fallen, from Alexander the Great and Charlemagne to those of yesterday. It has appeared as local and widespread epidemics, and has always, in temperate regions especially, figured largely in mortality reports. It is, in many places, the greatest cause of death and its prevalence is notably increasing. Its cause is known, but definite and acceptable rules for prevention and treatment have not, as yet, been formulated. Taken as a whole it is the greatest medical problem of the day.

Pneumonia is an acute infectious disease, with definite symptoms and anatomic changes, due to the presence and exuberant growth of the pneumococcus in the pulmonary alveoli. It probably obtains entrance into the air cells of the lung from the upper respiratory pas-

sages, where it may be found, without producing any obvious deleterious effects, in a large proportion of healthy persons.

The pneumococcus is cultivated with some difficulty and, apparently, does not lend itself readily to sapro-

phytic existence, although it is certainly found in this state. It has not been found, so far as I know, in the air, yet it is certain that the bacterium is received into the system through the inspired air. Whether it is

Brooklyn.

transported by the air in the form of dust from the dried and pulverized pneumococcus-laden secretions, or as a spray of such secretions thrown off by an infected person in coughing, hawking or sneezing is not known. but probably either is sufficient to convey the bacterium

This was in the evening. I told him to give me time till the next morning, and I would make up my mind. In the morning, after consultation, I concluded to offer him the copyright for the unexpired time (only one year) for two hundred copies.

Now to what influences may this increased prevalence be attributed? That it is due to any general deterioration of the resisting powers of the populace to morbid

Chicago.

infections is disproved by the fact that the average duration of human life has been distinctly lengthened during these same years. It is likewise difficult to believe that there has been any general increased vulnerability to this particular bacterial infection. We are, therefore, driven to the inference that the pneumococcus

Washington.

conclusion is irresistible that the prevalence of this malady has notably increased during the period of time covered by this inquiry.

has become more prevalent, or that our opportunities for encountering the germ have been multiplied, or, more likely, that these are both operative in bringing

about the results mentioned. If the natural habitat of the pneumococcus is the upper respiratory passages of man, and if it here finds its best culture media, and if these pneumococcus-laden secretions are extruded in such manner that they find their way, as spray or

dust, into the respiratory passages of other unaffected persons, then the very general absolute and proportional increase of urban populations, the increased facilities for travel and the universal tendency for people everywhere, in city and in the country, to congre-

gate and mingle together, is clearly sufficient to account for much, if not the whole, of the increased prevalence of pneumonia.

Now, although this is a fair inference, yet we lack exact information on this point and a compilation of the

existing pertinent knowledge, together with well-arranged and devised series of investigations along these lines will certainly prove of value and may open up most important avenues of prophylaxis.

There is one contributory cause of pneumonia which, although not demonstrable, I believe to be operative and which deserves special mention; I refer to the weakening of the respiratory reflexes, especially during sleep, which follows chilling of the surface of the physically and mentally exhausted body.

CONCLUSIONS.

1. The fatality of pneumonia has increased but little if any during the past eighty years.

2. The prevalence of pneumonia has steadily increased during the past fifty years and during the past twenty years this increase has been very great.

3. For individual prophylaxis the nasal, pharyngeal and oral cavities should be kept as free as possible from accumulations of mucus, and when it has been demonstrated that such secretion contains the pneumococcus such efforts should be especially well directed and maintained. In addition, care should be taken not to become chilled when overtired. The individual should, as far as practicable, keep out of range of the extruded pneumococcus-laden secretions of infected individuals. The sputum and other secretions of the respiratory surfaces

of pneumonic patients, or of other infected individuals, should be destroyed before it has been allowed to become dry. Such persons should cough and sneeze into a moistened cloth.

4. For communal prophylaxis the information and advice above given should be kept before physicians, with the request that, if they can consistently do so, they give it as their instructions to their patients.

5. That there may be some comparatively simple means by which pneumonia may be prevented, but that the fundamental information on which prophylactic rules may be formulated is not yet at hand; therefore it should be the province and duty of public health officers to seek assiduously for such knowledge, and I would suggest that, as a preliminary step in this direction, pneumonia be placed on the list of notifiable diseases and that the environment of pneumonic patients be carefully noted and the results analyzed.

Antidote for Formaldehyd.—In view of the fact that this chemical is coming more and more into general use as a disinfectant and antiseptic, cases of poisoning from it will become more frequent. We have an easily-accessible and reliable antidote in ammonia water. It may be given in the form of ammonia water (a few drops well diluted) or the aromatic spirit or a solution of ammonium acetate.—*Merck's Archives.*

PNEUMONIA.

ITS INCIDENCE, MORTALITY, PROPHYLAXIS.*

JAMES J. WALSH, M.D., PH.D.
NEW YORK CITY.

The mortality from pneumonia is distinctly on the increase in all our large cities. This increase is taking place notwithstanding the fact that mortality from other infectious sources is decreasing. We hear much of diphtheria and smallpox. Their ravages are as naught to pneumonia. While the death rate from such important causes as heart disease, brain disease and consumption is on the wane, that of pneumonia is constantly on the increase. There is no doubt now that pneumonia is an infectious disease, yet notwithstanding the decrease in mortality in other infectious diseases, pneumonia is becoming a universally more serious danger.

INCREASE IN MORTALITY.

It is true that the pneumonia mortality is on the increase, especially among the old, and that the improved sanitary conditions in our cities have raised the age limit to a marked extent. The increase of persons living above 60 in our cities is not, however, as has been shown by the Chicago Department of Health, enough to explain the even greater increase of deaths from pneumonia at all ages. The survival of many delicate children who formerly perished in infancy also adds to the pneumonia death rate, but not enough to account for the present additional mortality. In a generation that has seen the mortality in our large cities cut in two and has been informed by the last census that the length of a generation has increased from about 31 to over 35 years, and that has seen the death rate from consumption so much lessened as to make us confident of eventually preventing the ravages of the "great white plague of the north," tuberculosis, pneumonia continues to be an ever more threatening factor. In the words of Professor Osler, pneumonia has now taken the place of tuberculosis in what Defoe described as "the Captain of the Men of Death."

These considerations of themselves are sufficient to justify us in treating the problem of the prevention, or at least the lessening, of pneumonia as the most important sanitary question before the present generation.

CONTAGION OF PNEUMONIA.

While it is well known and recognized that pneumonia is an infectious disease, the possibilities of its contagiousness are still in doubt. The best clinicians all over the world are agreed that it is. Among young soldiers in France and Germany, where patients are liable to be in a condition of low resistive vitality, living rather crowded together in old, unsanitary barracks, a number of concomitant cases of pneumonia have been reported each year for many years, that seem to be of the nature of an epidemic. In the wards of hospitals in many parts of the world the admittance of a case of pneumonia, even when this affection was not due to grippe, has been known to be followed by the occurrence of other cases among the patients in the same ward. At public schools a series of cases of pneumonia have been seen occurring under such circumstances as to lead to the thought that an epidemic of pneumonia was at work. One school last winter obtained an unenviable notoriety by having two series of pneumonia cases within its walls.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee: Drs. Arthur R. Reynolds, George Cook and Heman Spalding.

It would seem important, then, first of all to insure precautions against the spread of the disease by teaching the general public that there is always an element of contagion-danger in a pneumonia case, and that certain protective and prophylactic measures are at least eminently advisable in order to avoid all danger. The secretions of pneumonia patients should be thoroughly sterilized by heat or should be subjected to strong chemical antiseptics. The expectoration of pneumonia reeks with bacilli. It is often received into napkins or handkerchiefs, and must not be allowed to dry and find its way into the air, but must be carefully disposed of by those in attendance on the patient. Practically the same precautions as are now invariably instituted with regard to tuberculosis should be suggested for pneumonia.

Such directions will doubtless seem exaggeration of caution, not only to the general public, but to most medical men. Let us remember that the profession generally would have been quite as opposed to the suggestion of these precautions with regard to pulmonary tuberculosis twenty-five years ago. Now every one realizes that the old position in the matter was a serious mistake and founded on an erroneous opinion tenaciously held. The same thing may prove to be true of pneumonia.

DUST AS A CAUSE.

It is often assumed that pneumonia is almost exclusively a disease of cold weather. 'Because, like other infectious fevers, it usually starts with a chill, it is often thought to be due to that charity mantle in etiology, the catching of a cold. As it affects the respiratory region this idea of a cold in its etiology is confirmed. It is well known, however, that pneumonia is by no means limited to very cold weather, but, on the contrary, may occur at any season of the year, when the conditions for its development are present. It is most frequent in the spring and the fall. Very cold weather is not the time when pneumonia is apt to be prevalent. It occurs particularly after a series of days without sunlight. This is usually damp weather, and the dampness is supposed to favor the taking of colds—hence the pneumonia. As a matter of fact, however, it would seem that the absence of sunlight and the presence of moisture favors the growth and multiplication of many micro-organisms, and among them especially the pneumonia pneumococcus.

It is well known that this micro-organism occurs in the throats even of healthy individuals. It seems, probably, however, that when there are large numbers present the risk of a pulmonary affection is greatly increased. Micro-organisms do not grow apart from the presence of organic material. The occurrence of street dirt rich in organic material, as is true of city streets, constitutes an especially favorable culture medium. We do not know that the pneumococcus would grow thus as a saprophyte, but there is reason to suspect it from its universal occurrence. In the absence of sunlight germs grow luxuriantly, and consequently the special tendencies to the occurrence of pneumonia in the spring and fall.

PROPHYLAXIS AND CLEAN STREETS.

At other seasons of the year it would seem that dust constitutes one of the disturbing agents for such germs. It is well known that windy days are apt to be followed by a series of pneumonia cases. It has usually been said under these circumstances that the irritation of the respiratory tract by the cold air which found its way in, was the prime factor in the production of pneumonia. Windy days, however, in which the wind is not

necessarily cold, has been known to give rise to an increased incidence of pneumonia.

The question of clean streets, then, would seem to be an extremely important basic principle in the general prophylaxis of pneumonia. The street-cleaning commission of our large cities is in this matter the sanitary bureau of first importance. A time will probably come when the city sanitary engineer will consider it quite as objectionable, or even more undesirable on the score of public health, to have dusty streets as to have malodorous drains and other such presumably serious unhealthy conditions.

INFECTION IN CROWDED ASSEMBLIES.

There are other forms of dust inhalation to which special attention will have to be given. The history of many cases of pneumonia have as one of their features the presence of the patient in a crowded hall, theater, church or some numerous assemblage within a few days before the development of the affection. The germs of the disease evidently get into the air in such places with more frequency than under other conditions and are taken up by the respiratory mucous membrane. In normally healthy individuals they fail to develop. In those, however, who are run down from overwork, or worry, or some serious pathologic condition, or whose vital resistance is lowered by old age, or some already existent respiratory affection, the germs of pneumonia find a favorable soil for luxuriant growth.

The conditions under which patients enter and leave such assemblies are especially favorable for the bacteria to obtain a foothold in the tissues. Not infrequently in colder weather, the mucous membranes are blanched by contact with the cold outer air, and while in this anemic condition become covered with whatever germs may be clinging to the dust particles of the room. Before the normal reaction occurs that restores the usual amount of blood to the respiratory mucous membrane, some of the germs may easily have secured a lurking place beneath the outer layer of cells. After the exposure to the germ-laden atmosphere on the exit from the theater or other meeting place the cold air is once more encountered and the circulation in the respiratory mucous membrane is once more interfered with by the contraction of the peripheral vessels and the consequent blanching of the tissues that takes place.

It is evident, then, that these meeting places must have special attention from boards of health if the dangers involved in the breathing of a dust-laden atmosphere in which many organic particles find a place, are to be avoided. Unfortunately theaters, because of economic conditions in our large cities, are so built that they are entirely beyond the cleansing bactericidal influence of direct sunlight. The result of this is that they may very easily become ideally favorable breeding places for many forms of germs and are undoubtedly the source of many of the colds and also of the pneumonias of the winter time. Churches are prone to be rather dark structures also, and though the sunlight has more chance to purify the air, its presence is not encouraged to any great extent.

It seems not improbable, therefore, that in the future regulations may have to be made requiring the arrangement of meeting places in such a way that they can be subjected for several hours each day to the influence of direct sunlight. Not only this, but it is probable that the present custom of heavy upholstery and thick, permanently-laid carpets will have to be discouraged. On the other hand, well-polished hardwood floors and readily removable rugs and matings are ideally san-

itary for such places. The floors will have to be of a kind that can readily be cleansed without the necessity of raising too much dust, and whatever dusting is done will have to be finished many hours before the crowd is to assemble.

Such regulations may seem far-fetchedly theoretic and perhaps unjustified by present conditions. The physician who announced twenty-five years ago that the spitting nuisance in public places would have to be regulated by law, would surely have been laughed at, as suggesting a Utopian idea, rather esthetic than sanitary. The present increase from mortality by pneumonia in our large cities justifies the taking of the most serious precautions. It is along the lines of thought suggested by the questions of the association of dirt and dust with pneumonia that the most hopeful prospects of prophylaxis and improvement of present conditions seem possible. Crowded centers are more liable to pneumonia because of the fact that the secretions of human beings are in themselves dangerous and their accumulation, even in impalpable dust, may prove a source of very serious danger.

GAS LEAKAGE AND DEFECTIVE DRAINAGE.

There seems to be no doubt on the part of many clinicians and sanitary authorities that defective house drainage forms one of the most prominent sources of predisposition to pneumonia. The statistics of the workmen in the Paris and London sewers and of the small army of men employed on the sewage farms of Berlin do not show any special prevalence of the disease. It seems probable, then, that general sewage, with its large abundance of watery elements holding most of the gaseous constituents present in solution, is not particularly dangerous. The more concentrated sewage of house and the leakage into house drains of various irritating ingredients from house illuminating gas would seem to be the worst etiologic factor.

It is a matter of record now that millions of feet of illuminating gas escape beneath the pavements of our cities each year. In the residence district pavements are apt to be of asphalt and so hermetically seal the gas in the soil. Its only mode of exit, then, is through the walls of houses and into branch sewers, from which it finds its way easily into living rooms. This irritant material keeps the lungs in a low state of congestion rather favorable to the growth of the pneumococcus should it once obtain an entrance into the lungs. It seems probable that sanitary authorities will have to take account of the gas leakage in their attempt to lessen the incidence and mortality from pneumonia.

DISCUSSION

ON PAPERS OF DRS. WELLS AND WALSH.

DR. N. S. DAVIS, Jr., Chicago—The conclusion Dr. Wells has arrived at is particularly interesting—and it seems perfectly justified by the figures which he quotes—that the mortality from pneumonia is not increasing. I think the opinion of the profession has been—as certainly my own has been—that it was increasing. One thing to bear in mind, however, is that the statistics before 1830 are of comparatively little use, because until a method of differentiating between pneumonia and a number of other diseases, especially pleurisy, was shown by Laënnec and generally understood, proper records could not be kept. Moreover, it was not until near the middle of the century that reliable statistics began to be gathered by public officials. The statistics of Dr. Wells between 1835 and 1855 will probably be found, if closely examined, to contain an over-statement of the mortality from pneumonia. As a consequence a more abrupt descent of the line of mortality than is represented on these charts would be correct. On the other

hand, mortality from pneumonia is more frequently recognized by physicians than formerly. Many cases were overlooked—especially cases that occurred in old age and that followed injuries and surgical operations. All these are now included and tend to increase the death-rate in the more recent returns over those of the earlier years. It is possible, therefore, that if we had more accurate information, which it seems impossible to get now, it would be found that this line of increase is exaggerated.

There is little to add in regard to prophylaxis. The subject is one of extreme importance, and one we ought to talk about, not only in the profession, but among laymen with a view of inducing them to adopt prophylactic measures. I believe with Dr. Walsh that, not only for the purpose of lessening the mortality from pneumonia, but decreasing other diseases as well, the greatest care should be taken in regard to the sanitary condition of places and vehicles where large numbers of people are wont to be gathered together. This is particularly necessary in regard to street cars which are badly ventilated, often very foul and very crowded; no places are more apt to become centers for the spread of infectious diseases.

DR. GEORGE M. KOBER, Washington—My impression, gathered from studying the official census statistics, is that there is a decided increase in the mortality from this disease within the registration area, and this is all the more surprising as there has been a marked decrease in the death-rate from consumption and all other infectious diseases and the span of life since 1890 has been lengthened about five years. The probable causes of the increased prevalence of pneumonia and its greater fatality have been well stated by previous speakers. One fact worthy of consideration is whether the increasing quantity of alcohol consumed in this country, amounting to over 17 gallons per capita, may not be a predisposing factor. An analysis of the mortality statistics shows that there is an increase in diseases of the heart, liver and kidneys and dropsies. These are diseases influenced by the undue consumption of alcohol, and in regard to pneumonia those who have had experience know that alcoholic subjects are exceedingly unpromising cases for treatment and usually succumb to the disease. This would seem to bear out the idea that alcohol is a predisposing factor in its production. But whatever the cause for the undue prevalence of pneumonia may be, greater effort to prevent the spread of the disease should be made by scientific disinfection and the adoption of general and individual prophylactic measures.

DR. A. ROBIN, Newark, Del.—In examining sputum at the Delaware State Board of Health Laboratory, I have frequently observed pneumococci in normal sputum. The pneumococci, when isolated in two or three instances, proved pathogenic to rabbits. This fact shows that the human being enjoys a natural immunity from pneumonia, except when that immunity is reduced by exposure or disease. I incline to agree with the view expressed by the Chairman (Dr. A. R. Reynolds) in one of the bulletins of the Chicago Board of Health concerning the relation of gripe to pneumonia. It is possible that influenza reduces the vitality of the organism, rendering it more susceptible to pneumonia, or the pneumococcus is rendered more virulent by a symbiosis with the bacillus of influenza. Another point I would call attention to is that many patients who die from pneumonia die from toxemia rather than consolidation, the latter in itself not being sufficient to cause death. A case has come under my notice in which a patient, a robust and previously healthy woman, contracted pneumonia after an attack of gripe, and succumbed on the fourth day of the disease, or long before consolidation was far advanced. In these cases the respiratory difficulties are due to a paralysis of the respiratory centers.

DR. H. M. BRACKEN, Minneapolis—Dr. Walsh has given us statistics in regard to the cities. It may be well to add something about the country districts. I regret that I have so little data to offer, but I have had occasion to note the statistics for Minnesota. This state has in the past had a small number of cases of pneumonia as compared with eastern states, but about a year and a half ago I noticed that the deaths from this cause appeared to be on the increase. I wrote and spoke on the subject to physicians in the small villages and rural districts of

the state, and the general opinion expressed was that there had been more pneumonia of late than formerly. The rate of mortality, it is also agreed, had been much higher than previously.

DR. WELLS—I have very little to add except to dwell for a moment on the question brought up by Dr. Davis as to diagnosis and its bearing on the accuracy of my statistics. In gathering the statistics from England and Wales for the early days of the past century I was particularly careful in the conclusions I drew. I always compared the mortality from pneumonia with that from other diseases of the respiratory tract with which it might be confused. I noted as far as possible the symptoms described and in this connection I may allude to the work of Dr. Cleghorn on the island of Minorca, in 1744 and 1745. He has given us a description of pneumonia which is, in some respects, well up to that given in most of the advanced text-books of to-day. The same is true of the descriptions given by Cullen, Brown and others, and in fact studying the literature on the subject one is forced to the conclusion that, comparatively speaking, pneumonia was as easily recognized in days past as it is now. My observation is that even in these days a pretty large proportion of physicians make a diagnosis on symptoms that might have been recognized as well years ago as now. Personally, I am of opinion that the diagnosis of pneumonia, for statistical purposes, was fairly accurate in the earlier years of the last century, and that the figures I have quoted may therefore be relied on as showing the actual increase in the disease. The prevalence of influenza no doubt accounts for the great increase that has taken place in the last ten years; but the general increases have been going on gradually for a much longer period, thus showing that there must be some other factor at work.

VENESECTION.*

H. B. FAVILL, M.D.
CHICAGO.

I will not apologize for occupying your attention with a topic to which I am able to bring neither new facts nor satisfactory conclusions. My excuse is the importance of the subject.

You will agree with me, first, that there has been during the last few years a tendency to place a greater value on bleeding; second, that the indications for its use are vague and indefinite as now defined in the literature, and you may agree, third, that it is of the utmost importance that this procedure of recognized value be not again discredited by indiscriminate employment in obviously inappropriate conditions.

Nowhere can one glean a more instructive lesson than in following the steps of Trousseau as he slowly drew away from the then dominant views as to venesection, sifting out with his rare judgment the real from the apparent and finally taking a stand that was quite out of harmony with his contemporaries. It is noteworthy, however, that his reservations as to the value of bleeding were in general centered on two aspects of the subject: the antiphlogistic, which he did not subscribe to, and the purely mechanical, as, for instance, the value of bleeding to check or remove cerebral hemorrhage, which he likewise discredited. Both of these reservations he fortified by convincing experience, not only as to non-efficacy, but with a positive opinion that patients so treated progressed less favorably than others. It is not likely that on these aspects of the matter his judgment will be found faulty. At that time, however, there was hardly considered the specific relation of the blood vessel contents and the inadequate heart.

Time has developed a view that there is a condition liable to occur in which there is, for various reasons, an

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. Frank A. Jones, George Dock and J. M. Anders.

ber in the *Medical News*, entitled "The Treatment of Pneumonia." My experience with the withdrawal of blood in pneumonia shows that it will not only benefit the patient's symptoms but also the physical condition of the lungs as shown by the physical signs. I do not pretend to be able to explain what reaction follows this procedure, but I maintain that when the lung is in a state of congestion and we allow a moderate amount of blood to leave the body there will be an almost invariable cessation of the advancing consolidation for a considerable period. I do not mean to say that it cuts short the course of the disease; it apparently delays consolidation. If one studies the physical signs over a particular region of the lobe he will find that consolidation does not go on to maturity, and that the breathing is better for a period of twelve to eighteen hours after the withdrawal of blood; but subsequently consolidation will occur. Any measure that delays consolidation on the fifth, sixth or seventh day of a pneumonia is a valuable one and may save lives. I think that if we can delay the consolidation and, at the same time, relieve symptoms by the withdrawal of blood we should do so. In my experience the withdrawal of from 200 to 300 c.c. is productive of as much good as the withdrawal of 500, 600 or 700 c.c. There is but little danger in the withdrawing of small amounts. Without being able to explain it, I feel convinced that the good which follows this procedure in certain cases is undoubted.

DR. T. B. GREENLEY, Meadow Lawn, Ky.—In severe cases of pneumonia, in olden times, when patients would be suffering with pain in side, difficult breathing, with rapid pulse and high temperature, the withdrawing of 15 or 20 ounces of blood would greatly modify these symptoms, rendering the patient much more comfortable. In those days the mortality did not exceed more than 10 per cent., but now fully 20 or 25 per cent. die. I think, in many cases of this disease, the restoration of the lost art would prove beneficial. I observed in the mortality reports in the city of Louisville last winter more cases of pneumonia died than those from tuberculosis.

BLOOD-LETTING AND BLISTERING IN THE TREATMENT OF PNEUMONIA.*

JAMES TYSON, M.D.
PHILADELPHIA.

There are two periods in the course of a croupous pneumonia in which blood-letting may be of service; first, in the early stage for the relief of pain and dyspnea, and second, in an advanced stage where there is engorgement of the right heart, also associated with intense dyspnea and general venous stasis.

No remedy is so efficient for the first object as blood-letting by the application of cut cups. Poultices, counter-irritation by the various measures commonly employed and even full doses of morphin hypodermically, are comparatively valueless as compared with wet cupping. Full doses of morphin produce temporary relief, but it passes away as soon as the effect of the drug wears off. No one who has not seen the happy result of such a bleeding can realize it. Venesection at the arm is less efficient, although it, too, relieves engorgement and diminishes pain and dyspnea. By no means every case of pneumonia, however, demands such treatment, and it is especially the cases associated with pleurisy—pleuropneumonia—in which it is indicated and is of such signal service.

The second period in which blood-letting is of service in pneumonia is, as stated, the advanced stage, where there is engorgement of the right heart, which is unable to unload itself of its burden, because the lung is already gorged with blood which it in turn can not get rid of.

The symptoms of this condition are an intense dyspnea, the breathing rate being often 50 and more, the breathing itself labored and shallow, the lips and face and even the general cutaneous surface dusky, and the pulse frequent and its volume feeble. No situation is more exacting of good judgment and decision than that described. Many physicians do not arise to the occasion and allow their patients to perish. I am afraid there have been occasions in which I have been wanting. Some of the failures to take advantage of opportunity may be due to the modern fear of blood-letting, which is as exaggerated as was its abuse, seventy-five years ago. With our present conservatism as to blood-letting it is scarcely possibly to do harm, and some opportunities to do much good are lost.

Blood-letting under these circumstances, and when I say blood-letting I mean general blood-letting, or venesection, is more efficient when associated with hypodermoclysis of normal salt solution and with oxygen inhalation. Hypodermoclysis alone, although of recognized value in cases of collapse from hemorrhage and after various surgical operations, can not be expected to be of advantage in such a state of pulmonary engorgement as that described. Indeed, I regard it as harmful because it must tend to overload the right heart, increase its embarrassment and possibly stop its action. After a blood-letting, however, the absorption of the fluid infused is more rapidly carried on, the toxins are diluted and eliminated in the urine and sweat, and in favorable cases the pulse improves and its rate diminishes, while the breathing becomes deeper, less frequent and less labored. I fear the accident referred to occurred in one case in my own practice, not a case of pneumonia, but of Bright's disease. The indication of mischief is sharp accentuation of the pulmonic sound.

The simultaneous inhalation of oxygen is an undoubted comfort to the patient, whatever be its influence toward cure of the disease. The lips become brighter red and the breathing becomes deeper and less labored. Dr. Clement B. Penrose, Baltimore, who has especially called attention to the combination of these three methods of treatment, says the patient is rendered much more susceptible to the influence of oxygen by the hypodermoclysis, especially if the oxygen be passed through a wash-bottle containing hot water to which has been added a teaspoonful of mixture of creasote and turpentine, each one part, and compound tincture of benzoin two parts. Dr. Penrose has also added a funnel to the oxygen apparatus, so arranged that the patient may inspire from it instead of through the tube introduced into the nostril.

These include the conditions in which I believe blood-letting may be found of service in the treatment of pneumonia. I do not claim that they are frequent in occurrence, but that they do occur I am confident, and believe also that by bleeding thus employed much suffering may be averted and a few lives saved.

As to blistering in the treatment of pneumonia, it is of limited advantage. It may be of service in connection with delayed resolution which is not due to a tubercular pneumonia. In the acute stages of pneumonia it is of no value.

DISCUSSION.

DR. EDWARD F. WELLS, Chicago—I would have liked to have heard more stress laid on the reasons for venesection, over and above those given by the lecturer. When the toxin of the pneumococcus was first brought to the notice of the profession, we became acquainted with its most poisonous effects; it causes a profound chill, a rapidly developing fever, and paresis of the capillary circulation. It would seem at this point that

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. A. W. Baer, A. B. Lyons and W. J. Robinson.

danger is most likely to creep in; the system may be overwhelmed by the intoxicant. The quantity of toxin in the blood may be the reason for resorting to venesection in the stage of hyperemia. It would seem reasonable to think that the greater the amount of lung involved, the more active would be the pneumococcus and the greater the quantity of toxin would be thrown into the circulation, and the more severe the symptoms would be. But this is not always the case. It seems as if a tolerance is set up at this time, but however this may be, we know that in the early stage, venesection is of the utmost value on account of the removal of the toxin. If we can take away, say the twentieth part of the blood of the body, and supply its place indirectly with normal salt solution, we diminish the amount of toxin and thus remove a source of danger. It will not be successful in all cases, because in some the last added portion of the pneumonia toxin is simply the last straw that turns the scale against the patient. I agree, however, with Dr. Tyson that this expedient will save life in a large proportion of cases.

DR. SOLOMON SOLIS COHEN, Philadelphia—Statistics have been published by men of high standing and by others not so great, of hospital patients treated for pneumonia, which seemed to prove that for the last hundred years the mortality of pneumonia, under all forms of treatment, has remained about the same—about 25 per cent. in hospitals—no matter what the treatment, or with no treatment. It should be remembered, however, that the given patient is something more than a mere unit in a column of statistics. I am convinced of the value of our therapeutic measures in pneumonia. I have seen lives saved by saline infusions, by venesection, by oxygen inhalations and by the combination of these measures, which I have been using for the last ten or twelve years, when indicated in the individual case. I have had opportunities of witnessing and of exhibiting to my classes many remarkable results, some of which are on record in published clinical lectures. I am sure that I have seen patients recover who, under the older methods, would have died. I have come to the conclusion that bad results in hypodermoclysis are often directly due to the use of a needle of too large a caliber and the consequent too rapid injection of the solution. I have found it best to use needles of moderate caliber and to inject the saline solution rather slowly. I prefer to inject from four to six or at most eight ounces subcutaneously in the course of twenty to thirty minutes, and this may be repeated several times in the day if necessary. This method is better than to give one large injection daily, as is usual. The mechanical obstruction to respiration, by the condensed lung, is the least source of danger to the patient. This is shown by the fact that after the occurrence of the crisis there is a marked change for the better in all the symptoms, without sufficient change in the physical condition of the lung to account for the improvement. The great danger is toxemia, which is the indication for venesection and hypodermoclysis. Venesection in the later course of the disease may be useful to relieve the right heart of the load put on it by the consolidation of the lung. Oxygen by inhalation will compensate when necessary for the respiratory loss caused by the pulmonary consolidation. It supplies condensed respiratory pabulum, thus reducing the work of the sound lung.

DR. HENRY BEATES, Philadelphia—In the emergency arising during the course of pneumonia, where the remedies referred to are necessarily employed, value attaches to the order in which they are used. This is exceedingly important. First, it is evident that death usually results under these conditions, because the heart is unable to carry the circulatory load, and therefore, with the venous side distended and the heart laboring, it is absolutely necessary to resort to prompt venesection. This not only diminishes the volume of blood in front of the heart, but, at the same time, gets rid of much of the toxin. The hypodermoclysis of normal salt solution should be carried on at the same time that phlebotomy is in progress, for physiologic reasons.

DR. W. W. TOMPKINS, Charleston, W. Va.—There is a marked difference in pneumonia between patients living in the country and those living in cities. The former are more likely to be benefited by venesection than the latter. Personally, I have had only one experience with venesection in the treatment

of pneumonia. It is a method which I will hold in reserve and use in suitable cases. Dr. Fenwick of London, England, exchanged practice with his son. The son was in the habit of bleeding his country patients and with good results; when he came to London he used the same practice, but with fatal results. In this particular series of cases it demonstrated that in a rural and country district, where the patients lead out-of-door lives, it was good, but in crowded London it was bad. This demonstrates that one class should be depleted, the other sustained and strengthened. All of which goes to prove that environment has much to do with the method of treatment.

DR. TYSON—The fact that the removal of blood in the first stage of pneumonia also removes a certain proportion of toxins with it, is undoubtedly true; but the toxic danger is not so great in the early stage as it becomes later. There is no doubt that, even in the early stage, there is a certain amount of danger from the action of the toxin. I agree with Dr. Cohen as to the caution to be observed in performing hypodermoclysis. This caution, giving small quantities several times a day of the salt solution, I have always observed in cases of uremia, where no immediate danger threatens the patient and there is more time for the application of remedial agents. My intense desire to give relief quickly led me to give the saline solution, without waiting to perform venesection, and governed my treatment; whereas bleeding might have been resorted to with safety and followed by the salt solution, and possibly with much better result.

THE DRUG TREATMENT OF PNEUMONIA.*

A. A. STEVENS, M.D.

LECTURER ON PHYSICAL DIAGNOSIS, UNIVERSITY OF PENNSYLVANIA.
PHILADELPHIA.

Croupous pneumonia is an affection of a dual nature: it is an acute specific fever, and at the same time an acute inflammatory disease of the lung. In formulating a rational treatment the dangers arising from each of these processes must be given due consideration. It is a well-established fact that the chief danger lies in the toxemia. The severity of this toxemia is dependent on the virulence of the infection and on the degree of reaction in the individual attacked, but it bears no relation whatever to the extent of lung involved. Cardiac weakness also contributes largely to the mortality of croupous pneumonia. In some instances this appears to result mechanically from the impediment offered to the circulation by the consolidated lung; more often, however, it is simply one of the local manifestations of the systemic poisoning. Complications, for the most part unpreventable, are the immediate cause of death in not a few of the fatal cases. Thus, endocarditis, pericarditis and meningitis are not infrequent; but as these affections are associated with the *Micrococcus lanceolatus*, any mortality that is due to their development must be credited also to the general infection. Finally, in rare instances, asphyxia caused by diminution of the respiratory surfaces is the chief factor in bringing about a fatal termination.

VARIOUS SO-CALLED SPECIFICS.

In view of these facts it is evident that any treatment to be really successful must be aimed at the infection itself or its resulting toxemia. Fortunately, in the majority of cases but little assistance is required of the physician, as Nature furnishes her own antidote so abundantly that the disease, after running a definite course, ends in complete recovery. In many cases this tendency to spontaneous resolution is so pronounced that it is not offset even by the most inappropriate drug-

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. A. W. Baer, A. B. Lyons and W. J. Robinson.

ging; on the other hand, the infection is at times so overwhelming in its virulence that death results despite the very best directed efforts. To-day one seldom hears of pneumonia being aborted by the timely use of veratrum viride. While this drug is undoubtedly of value as a circulatory sedative in certain phases of the disease, it is difficult to believe that it has any power in hastening the occurrence of the crisis. Under its use I have occasionally seen the temperature fall to normal in three or four days, but this has occurred quite as often under an expectant plan of treatment.

The treatment of pneumonia by large doses of digitalis, originally proposed by Petresco of Bucharest, has never had many advocates in this country. In 1894 Petresco reported 1,192 cases treated by this method with a mortality of 2.66 per cent. But the author himself states that the treatment is not applicable to very grave cases, and that his observations were made in a military hospital on young and robust men. Petresco's figures lose much of their significance when we compare them with the death rate in the German army, which, according to Osler, was only 3.6 per cent. in 40,000 cases of pneumonia among healthy picked men.

Aufrecht, in Nothnagel's Special Pathology and Therapy, ardently advocates the hypodermic administration of quinin—8 grains, once or twice a day—not as an antipyretic, but as a specific remedy. According to Petzold¹ the mortality under this treatment in 261 patients treated in the Altstadt Hospital of Magdeburg was 8.8 per cent., but we learn from Strusberg² that in the medical clinic at Bonn during the same period the mortality under symptomatic treatment was only 7.97 per cent. I have used the carbonate of creosote, which has been so highly extolled by Van Zandt and Weber in 9 cases; of these 2 died. The daily dose was from 40 to 60 minims. While no untoward effects followed its use, in no instance was the crisis hastened by the drug or were any of the symptoms of the disease appreciably influenced by it.

SEROTHERAPY.

Of all the specific treatments that have been recommended for croupous pneumonia that by antipneumococcic serum was the most promising. It aimed directly at the essential factor in the mortality, the toxemia. Perhaps sufficient time has not yet elapsed to warrant a final opinion on this treatment, but certainly those who have given it a fair trial will admit that it has fallen considerably below their expectations, and that it has yielded results in no way comparable to those obtained in diphtheria from the use of antitoxin. In a very fair test made by Dr. James C Wilson³ in the German Hospital of Philadelphia the mortality in one series of 18 cases was 22.2 per cent. and in another series of 18 cases 35.3 per cent. Sears⁴ of Boston has recently reported a series of 12 cases with a mortality of 25 per cent. The results obtained under these so-called specific treatments coincide so closely with those that have often been obtained under symptomatic treatment, and have been so variable in the experience of different observers, and even in the experience of the same observers working at different periods, that we are forced to conclude that the figures do not indicate any relation whatever between the remedies employed and the mortality reported. If such statistics possess any value it is in emphasizing the fact, well known but often forgotten, that the mortality of croupous pneumonia is

exceedingly variable, fluctuating between 4 or 5 per cent. in the young and robust and 75 or 80 per cent. in the old and debilitated.

GENERAL EXPECTANT TREATMENT.

Although we have yet no specific remedy, much may be done in the way of symptomatic treatment to avert a fatal issue. In a large number of cases no drugs are needed. By confining his services to the careful supervision of the sick room, to the selection of nutritious but easily digestible food, to the recommendation of appropriate external applications, and to the critical study of the symptoms from day to day, the medical attendant will as conscientiously discharge his duty to his patient as he will by systematically prescribing drugs, which, even if they do no harm, can not possibly be of benefit. Until we come into possession of so powerful a weapon as is quinin in malaria, as antitoxin in diphtheria, or the salicylic compounds in rheumatism, our position in regard to the treatment of pneumonia had far better be one of armed defence rather than one of heroic aggressiveness.

The symptoms that most often demand individual attention are the pain, cardiac weakness, cough, fever, dyspnea, insomnia and delirium. If the pain be severe and fail to yield to local remedies, morphin should be given hypodermically or Dover's powder by the mouth. This treatment will serve also to subdue the restlessness and anxiety that often mark the onset of the disease, and which, if allowed to continue, tend to augment the exhaustion.

THE CARDIAC SUPPORT.

The most important indication in the symptomatic treatment of croupous pneumonia, and the one most difficult to meet, is to counteract the cardiac weakness. Alcohol is regarded by most clinicians as the best stimulant. The question whether this drug is a food or a poison need not be discussed here. If its reputation as a useful stimulant in croupous pneumonia and similar infections has not been fully established by the accumulated testimony of the past fifty years, then surely "experience is fallacious and judgment difficult." Often it is not required, but when the pulse becomes compressible and dicrotic, and the second sound at the pulmonary area loses its force, it should be given freely. The patients who need it most are the old, the debilitated and the alcoholic. Often three or four ounces of good whisky in the twenty-four hours will suffice, but in some instances two or three times this amount may be given with advantage. I know of no better rule for administering it than that laid down by Brunton: "Sit by the side of your patient for a while and watch him after the administration of a dose of alcohol, and if you find that the alcohol brings back the various functions nearer to the normal, then it is doing good; if the functions of the organs diverge further from the normal after the administration of alcohol, then it is doing harm."

After alcohol our thoughts naturally turn to digitalis. While this remedy is undoubtedly useful in some cases, its action is uncertain and often disappointing. In my experience it has been almost invariably badly borne when administered for the irregular flagging pulse of the period immediately following the crisis. Its frequent failure at other times may be explained by the fact that the cardiac insufficiency in the majority of cases is not dependent on simple dilatation or relaxation of the ventricles, but on degenerative changes in the myocardium, or perhaps, in some instances, on disturbances

of the motor ganglia of the heart, brought about by the infection. Often no gross lesions are found postmortem in the heart when there have been during life most pronounced symptoms of circulatory failure; moreover, the symptoms of cardiac embarrassment often disappear on the occurrence of the crisis, even though the consolidation in the lung still persists. Mechanical distension of the right ventricle undoubtedly does occur in some cases. It may be recognized by the enlargement of the area of cardiac dulness, by the marked cyanosis, the orthopnea and the small pulse. In this condition digitalis, by driving the blood with greater force against an impassable barrier, is likely to do harm; it is better to relieve the strain on the right ventricle by judicious venesection.

As a circulatory stimulant, strychnin generally proves more efficacious than digitalis. It should be given in ascending doses from 1/60 to 1/15 of a grain, careful watch being kept for the appearance of any untoward symptoms. In order that there may be immediate absorption large doses should always be given hypodermically. Caffein is a useful adjunct to strychnin, but, of course, it should not be used when there is cerebral excitement or insomnia. In threatening collapse I have found no stimulant so generally serviceable as camphor. It is especially useful in tiding the patient over the profound depression that often accompanies or follows the crisis. It is available also when pulmonary edema arises as a complication, and in this condition it may be advantageously combined with atropin. To secure the best results camphor should be given hypodermically, dissolved in ether or sterile olive oil, in doses of from 1 to 2 grains every two or three hours. In the absence of pulmonary edema subcutaneous saline infusion may be tried for its effect on the heart and the secretions; personally, I have never seen any definite good follow its use in pneumonia.

REMEDIES FOR COUGH, FEVER AND DELIRIUM.

The cough varies considerably; in many cases it is not sufficiently troublesome to require any special attention; on the other hand, it may be the most distressing symptom of the disease. For the hard, dry cough, especially of the first stage, no remedy is so useful as opium in the form of Dover's powders. Expectorants are rarely needed. The inflammatory exudation in the air vesicles is removed almost entirely by absorption, and to attempt its expulsion by means of drugs is useless. When, however, there is a good deal of bronchial catarrh with much viscid sputum, ammonium carbonate may be given to facilitate expectoration, but it should be withdrawn immediately if it cause any disturbance of digestion.

It is difficult to determine how far the fever itself is responsible for the disturbance of nutrition, but the fact that in a very large proportion of the gravest cases the temperature is not high indicates that the chief factor in bringing about the exhaustion is not the fever, but the toxemia. This being the case, and as the febrile period is generally of a comparatively short duration, the temperature is better disregarded entirely, or if treated at all, reduced by means of cold or tepid sponging. Experience is strongly against the use of such active antipyretics as antipyrin and phenacetin. By favorably influencing the pulmonary circulation, drugs that are employed in counteracting cardiac insufficiency are also of service in relieving the dyspnea. Naturally, the circulatory stimulants that are also respiratory stimulants, like strychnin and caffein, are the most useful. Oxygen makes the breathing easier, lessens

cyanosis and conduces to sleep, and to this extent aids in conserving energy.

When insomnia and delirium are sufficiently severe to demand the use of drugs, morphin will generally be found the most efficacious. It is generally conceded that this drug is useful during the first two or three days of the disease in relieving pain and in subduing restlessness, but many clinicians condemn its use in the later stages of pneumonia, contending that it depresses the respiration, checks secretion and paralyzes the bronchi. Waiving theoretical objections, I have often used it with the greatest satisfaction in quieting delirium and in securing sleep. Sometimes the invigorating effects of a few hours of sleep secured by a single injection of morphin are truly remarkable. Of course, morphin should not be used when there is extreme dyspnea or when there are evidences of pulmonary edema. Next to opium I prefer chloral. Doses of from 10 to 15 grains are rarely followed by an appreciable circulatory depression, especially if given in conjunction with digitalis.

Delayed resolution is a troublesome complication. Fortunately it is of rare occurrence. In the few cases that I have personally treated resolution has ultimately taken place under repeated blistering and the free use of tonics. Riess has recommended injections of pilocarpin and Dieulafoy, Forbier and Lepine the production of aseptic abscesses by means of turpentine injections, but with these methods of treatment I have had no personal experience.

DISCUSSION.

Dr. W. J. ROBINSON, New York—Although, generally speaking, I have the highest respect for the opinion of Professor Klemperer of Berlin, who introduced the serum treatment for pneumonia, I have no hesitation whatever in saying that the antipneumococcic serum is perfectly useless in the treatment of pneumonia. I base this opinion on the fact that pneumonia is not due to a single bacillus and the danger is not due to a single cause; and, therefore, it is not suited to specific treatment. But it is not only theoretically objectionable; clinical experience has shown it to be followed by bad results. Several fatal cases have been reported. There is no analogy whatever to the use of antitoxin in diphtheria, because in this disease the danger is from a single cause. At present the rage for serums for all diseases is only a fad and is not destined to last long. The value of drugs is difficult to weigh in self-limited diseases, and when the case recovers it is difficult to say whether any given drug has been of value or not. As regards the use of drugs in pneumonia, my own impression is that creosote and its derivatives give the best results. The administration of hydrogen peroxid has been recommended on the theory that it would become decomposed in the stomach and would yield oxygen to the blood. I have not myself been able to obtain any results from its use.

Dr. E. F. WELLS, Chicago—I have little confidence in the statistics of pneumonia as bearing on mortality under different modes of treatment. I collected statistics of nearly four hundred cases of pneumonia, some years ago, and found that most of the cases reported in medical journals had been published for the purpose of bolstering up some special method of treatment. We can see the fallacy of statistics when the unfavorable cases are not reported. On the other hand, we have statistics from hospitals dealing with a large number of cases, and in which a very large proportion die. The unreliability of deductions from such statistics is shown by the great difference in mortality in different groups, the rate varying from 3 to 95 per cent. Hospital statistics and cases published in the journals must be set aside as of little value for our purpose. With regard to the relative mortality in the robust and delicate patients, my experience in this matter has been different from that of the reader of the paper. I have observed that it is the robust and not the delicate subjects that are more likely

to drop off suddenly, while the weak are more likely to recover. As regards the means to be adopted for the relief of pain, their value is difficult to determine, as the pain in pneumonia is of short duration and usually ceases spontaneously within three days' time. If one gives a little morphin and the pain disappears in a few hours, he is apt to ascribe the relief to the drug, whereas it may not have been necessary, as the pain would have subsided without it. In cases of edema of the lung in pneumonia, do not forget the expedient of raising the foot of the bed, so as to enable the serum to flow out of the bronchial tubes.

One of the speakers said that pneumonia can not have a specific treatment because it is due to different germs and not due to a single cause. I, on the contrary, believe that pneumonia is the disease of all others, in which the authorities are agreed as to its cause, and that it is due to only one bacterium and that is the pneumococcus. One of the most remarkable effects of the pneumococcus on the human system is that its invasion is generally accompanied by a leucocytosis. It is when we have the initial chill that we find the notable increase in the leucocytes; it may be to treble the proportion found in healthy blood. This seems to be the natural means of resistance set up by the system to protect it from the pneumococcus. Whether or not we are doing the right thing in contracting the capillaries by giving digitalis at this time; or whether or not it would be better to give salicylic or nucleinic acid, which increases the number of the white blood-cells, is sometimes hard to decide. We know much about the pathology of pneumonia, but still have something to learn about its treatment.

Dr. H. C. WOOD, JR., Philadelphia—I would urge discrimination in the application of remedies; to treat the patient and the pneumonia is the safe rule to follow. I take exception to the statement of Dr. Cohen that the fact that the statistics for the last fifty years show no improvement in the results of treatment of pneumonia is to be disregarded. There is no proof our results in pneumonia are much better than those of fathers. We have no specific for pneumonia. The disease is of short duration and having no specific, the physician must be content with observing the symptoms and watching the course of the disease, guiding his treatment accordingly. If the temperature goes up, he gives a cold bath, or an antipyretic; if the heart becomes weak, he gives cardiac stimulants, and so on. We can watch the symptoms in pneumonia; but have very little knowledge of how to overcome them. If the heart is weak we give strychnia, forgetting that it is not the left heart that is giving out, but the right heart. It is a fact that we know very little about the effect of drugs on the right side of the heart. We do know, however, that, of some drugs, the effect on the two sides of the heart is different. For instance, nitroglycerin acts differently on the right side of the heart and on the left side. We really can do very little until we can settle this point. In my opinion, with the single exception of venesection, we have no remedy or method of treatment of unquestioned value in the treatment of pneumonia.

Dr. JOS. M. PATTON, Chicago—I can hardly agree with the last speaker that we know nothing about the treatment of pneumonia, for, in fact, we do know about some things that we can do with success. In a patient where we have one whole lung to carry on its functions, and the right side of the heart is not overloaded, about the only real danger to be feared is the toxin. As regards the drugs used, the continued administration of digitalis may be objectionable, through its action on the left side of the heart on which there is no strain. Strychnia does good because it equalizes the circulation better than any other drug. In fact, in pneumonia I have obtained the best results from large doses of strychnin better than from any other drug. With regard to alcohol there is a difference of opinion. I have personally very little confidence in its beneficial effect, except at the approach of the period of crisis, when it may occasionally be given with advantage. I have not seen any good result from its continuous administration. As to the antipneumococcic serum, I have not arrived at the conclusion that it is absolutely useless. It may prove to be worse than useless, but its position is as yet undetermined. We have reason, however, to expect that something may come out of it in future. The mere introduction of the aspirating needle into

the lung may, of itself, in cases of delayed resolution, do good by setting up a certain amount of irritation.

Dr. THOMAS F. REILLY, New York City—The outlook in any case of lobar pneumonia depends largely on the condition of the kidneys. In the very young the kidneys are almost always in good condition and the mortality from this form of pneumonia is practically nothing. It is rare to find perfectly sound kidneys in anyone after fifty years, and hence the mortality is very high. The kidneys of alcoholics are generally diseased and are unable to throw off the poisons and, as a consequence, the disease is generally fatal. The value of the saline injections spoken of is due largely to the diuresis that follows their use. With regard to the means to be employed to afford relief from pain, I have found much value in the topical application of the combination of moist clay, glycerin and aromatics, which is put up by several supply houses and can be put up by any druggist. The employment of exploratory puncture in two cases of pneumonia with delayed resolution succeeded in materially hastening resolution.

Dr. A. B. LYONS, Detroit—With regard to the mixture of glycerin and some base like kaolin, I think that if venesection will do any good by abstraction of blood, surely the application of glycerin will do good in the same manner. My own experience has impressed me very strongly in favor of this method of medication, and this form of relief especially. As yet there has been no official preparation of this kind, but we all know what it is: It is a preparation of glycerin, and we know that it is the effect of glycerin to draw moisture to itself, and when applied to the skin it draws serum from the blood, very much on the same principle as the use of a blister.

Dr. H. H. BUGGS, Asheville, N. C.—When I began the practice of medicine, in 1860, a book had just been published by J. Hughes Bennett of Edinburgh, which gave statistics of cases of pneumonia, in hospitals of Paris and elsewhere, in comparison with other cases treated by himself. The proportion of deaths under the usual treatment at that time with venesection and depressants, was about 33 or 34 per cent.; under the expectant treatment, in which nothing was done except to look carefully after the welfare of the patient, there was a mortality of only 23 or 24 per cent.; while under Bennett's supporting treatment the deaths were only 3 or 4 per cent. This coincides very closely with what Dr. Wood said; it is not so much the medicines that are used, as it is the care of the patient, which gives the best results. As shown by Bennett, even the expectant treatment showed much better results than the treatment generally pursued in those days. The principal object of Bennett's treatment was to support the strength, to watch the case, to take care of the secretions, to keep the patient quiet, and to see that he was never awakened unnecessarily. The results of his treatment were satisfactory and I am not aware of any statistics which prove that the treatment at the present time is any more successful than Bennett's. No specific has been found and until this has been done, there can be no better treatment. The important things are to take care of the secretions, to support the heart, to give suitable nourishment, and do the best to sustain the strength of the patient until the disease runs its course, which will usually be in a week.

Dr. W. W. TOMPKINS, Charleston, W. Va.—For a number of years I have been in the habit of going about among the medical men in the colleges and hospitals in order to take notes of different methods of treatment. I found in Baltimore, Philadelphia and New York that pneumonia was treated with different remedies, and when I returned at other times, they had changed to other remedies. I deplore a tendency to depend on special medicinal agents in the treatment of pneumonia. Personally, I believe that the only safe thing to do is to treat each individual case of pneumonia according to its special needs. I think that as regards the influence of age on mortality, the more advanced in life the cases are, the more likely we are to lose them. I urge especially the importance of looking after the heart's action and the careful nursing of the patient. When a patient with acute pneumonia gets well, the doctor is fortunate and the patient is more fortunate. I do not approve of cough syrups and mixtures, as they derange the digestion, and this causes a loathing for food. Keeping up the strength

of the patient by proper digestible and easily assimilable food are as potent factors in a cure as are drugs.

DR. HENRY BEATES, Philadelphia—I wish to ask Dr. Wells what type of leucocytosis he has found.

DR. WELLS—The ordinary form of leucocytosis occurring in pneumonia. I have found it within an hour of the onset of the attack. At the same time, or earlier, the eosinophiles are reduced in number, and in the course of a few hours are driven out of the circulation. It is at this time that the multinuclear cells, as motile secreting glands, are engaged in battle with the toxins of pneumonia. I look on this condition as of special interest and as not without diagnostic importance.

DR. STEVENS—In view of the obstacles in the way of the successful cultivation of the pneumococcus in artificial media I have grave doubts as to the genuineness of much of the serum sold as antipneumococcal serum. In reply to the question about hydrogen dioxid I have had no experience with it. I think that too much stress has been laid on the condition of the right ventricle of the heart. The chief danger lies not in the strain to which the right ventricle is subjected, owing to the mechanical obstruction in the lung, but in the toxemia which attacks the heart as a whole. As to the blood-count, I think it is a mistake to put too much stress on leucocytosis in the matter of prognosis. A marked leucocytosis does not always mean good reaction, nor a slight leucocytosis poor reaction. I believe, however, that hypoleucocytosis is to be regarded as an unfavorable sign. Of 11 cases with pronounced hypoleucocytosis that have come under my observation only one recovered.

(This symposium on pneumonia will be concluded next week by the article by Dr. E. Fletcher Ingals on "The Prognosis and Treatment of Groupous Pneumonia, with an Analysis of the Cases Treated in Cook County Hospital for Fifteen Months Preceding April 1, 1902," with the discussion thereon.)

EXPERIMENTAL RESEARCH ON THE HEART OF THE DOG.

WITH REFERENCE TO CARDIOTOMY AND CARDIORRHAPHY.*
BENJAMIN MERRILL RICKETTS, Ph.B., M.D.
CINCINNATI.

Nothing indicates more clearly the lack of confidence in surgical intervention in lesions of the heart than that they have been treated as anomalies. The best history of the surgery of the heart accessible to the general reader is to be found in a work that treats of anomalies and abnormalities. They of themselves show that the heart is more susceptible to injury, disease and surgical operation than generally supposed. Simple puncture with a needle was at one time thought to result in instant death; indeed, such thought generally prevails at this time. Infection in animals is more likely than in man because of the great difficulty in making them sterile and keeping them so after they have been operated on.

If experimental physiology and surgery has taught anything, it is to reason by analogy from animal to man. Animal experimentation has led the way to more successful surgical work and it will continue to do so. It not only shows what can be done, but it teaches by manipulation alone, if nothing more, how to do it.

There are many diseases and many lesions which do not manifest themselves or cause symptoms, which are readily discernible. In other words, the particular lesion is wholly unsuspected until it has advanced far enough to produce functional disturbances, which are often serious. Then search is made for the cause. Then, again, it is possible to diagnose certain diseases only by

the symptoms, caused by the functional disturbance produced by the lesion, and not by the lesion itself. The functional disturbances resulting from a given lesion are not always the same.

Pathologic physiology receives only scant attention or none at all in our medical schools, yet it is of the utmost importance. Only a few works on this subject are accessible, and these are unsatisfactory in some respects. Many questions of the utmost importance are unsettled. These remarks apply with peculiar force to the heart. The intimate connection of the function of respiration with the heart and the disturbance produced in the functions of the other, when either heart or lungs is diseased, is the reason for taking up both the normal and pathologic physiology of the heart.

Aspiration of the pericardium should not be attempted owing to the dangerous consequences, such as injury to the coronary, internal mammary and intercostal vessels, and puncture of the walls of the heart itself; and also, the possibilities of infection from the escape of fluid through the puncture into the pleural cavity and mediastinal space. The probabilities are that in many cases in which fluid has been purported to have been aspirated from the pericardium, that the fluid was contained within the pleural cavity, mediastinal space, pulmonary cyst or abscess or a pleural cyst.

The heart is very susceptible to alkaline solutions, which accelerate it. The absence of stomata in the diaphragm within the pericardium is to exclude fluids from the peritoneal cavity. The pleural fluids will, however, pass through the pericardium. In the lower animals (fish) the pericardium and diaphragm are wanting. As they ascend in scale the pericardium becomes more fully developed to form the pericardial sac; the same is also true of the diaphragm.

There is no way of determining whether or not the heart will absorb to any degree any fluid that may be contained within the pericardium. Neither have such observations been made on the ability of the pericardium itself to do so. It has, however, been determined that the heart will not withstand a high degree of pressure from fluid or otherwise within the pericardial space. It will stand a greater pressure if the pressure be gradually increased as in the case of pericardial effusion, resulting from pericarditis. It will, in a normal state, absorb more or less of its exudate, and it will probably have a greater capacity to absorb in a pathologic state.

Pressure from any source may be sufficient to force a part, or all, of the blood out of the cavities of the heart. This may be gradual or sudden, fatality resulting only when functional circulation can not be maintained. The consequences are less severe and serious trouble delayed if the pressure is increased slowly, as by the growth of new tissue. Rapid pressure is usually due to change in shape of the chest from trauma, or from concealed hemorrhage within the pericardial, pleural or mediastinal spaces.

OPERATIVE TECHNIC.

Asepsis.—Sterilization of the local area of the dog is almost impossible. The area should be shaved after the dog has a thorough bath, which is difficult to give to tramp dogs, as they are not accustomed to it. A sterile sheet, in which there is a hole large enough to operate through, should cover the dog. Alcohol or turpentine is applied to the shaven surface, which is then ready for incision.

Anesthesia.—Ether should be employed in all cases for operation, and carried to complete relaxation and chloroform given to produce death.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard.

Incision Through Skin and Muscles.—The incision should be made longitudinally, beginning at the third or fourth rib on the left side, and about one-third to one-half inch from the internal mammary and diverging slightly from the sternum down to the desired point, even to the apex of the heart. It may be extended to the attachment of the diaphragm and down to the costal cartilages.

The external soft tissues being divided are then reflected outward, great care being taken not to have the point of the knife slip into the chest cavity, as the heart, lungs or arteries may be injured.

Division of Cartilages and Bone.—Divide the third, fourth, fifth, sixth and seventh ribs, if necessary, great care being observed in opening the chest that bone spiculæ are not left to lacerate the heart during its pulsations, otherwise serious, if not fatal, laceration of its wall might ensue. Such an accident must be guarded against during the entire operative procedure. Great care must be taken to avoid such an injury to the pericardium also. It is, therefore, safer to completely sever the bony structures with a sharp cutting instrument than to fracture them by force or otherwise. The same precautions should be observed in dealing with the cartilaginous structures. If necessary, the cartilages may be cut near the left border of the sternum and retracted outwards to the right or left.

Mediastinum.—If the mediastinal space be opened the respiratory motion of the thin membrane that walls off the right lung may greatly interfere with rapid work. It will especially be so if overdistension of the right lung should rupture it. The right lung would then retract upon itself. It is, therefore, safer and less difficult if that space be not opened. The opening can, however, be closed with the hand of an assistant during the entire operation.

Hemorrhage.—The bleeding in the skin and muscle is seldom annoying. The intercostal arteries usually cease to bleed after they have been exposed to the air and sponge pressure; if not, they can be easily controlled by forceps. The internal mammary once wounded, the hemorrhage is great and troublesome to check, except in one way, namely, pull the skin to the right, having only the costal cartilage and muscles to constitute the chest wall, then with the finger, or a larger pair of acupressure or artery forceps, include all the tissues between the cartilages, just above the wound, in the forceps put on parallel to the long axis of the costal cartilage or in the transverse diameter of the chest. It may be necessary to do this above and below the wound, as the internal mammary artery may bleed a little from below, the anastomosis being rather free with the deep epigastric. After the hemorrhage has been checked it is best to apply a ligature *en masse*, as it saves time, which is an item with the heart exposed.

The first opening should give good view and room to work; if not, incise two inches to the left in the intercostal space and cut the ribs transversely with a pair of sharp bone forceps, beginning at the outer border of the incision in the intercostal space. If necessary, other ribs are divided so that a flap sufficiently large should be turned back to give ample room.

There is no occasion for using gauze or any kind of packing in heart injuries, much less so in pericardial injuries, as bleeding from the pericardium is insignificant except in cases of injury at the point of attachment of the extreme base of the heart; even then experiments show that hemorrhage from injuries to it are but slight. To secure beneficial results from gauze packing

in heart injuries it is necessary to employ firm pressure. To do this would interfere with the heart's action. Therefore, it would be more injurious than beneficial, because such pressure would force the heart back on the posterior wall of the thorax.

If a patient survives the immediate thrust of a stil-etto-like instrument, however small, the probabilities are that the hemorrhage will be less when the weapon is withdrawn at the end of several hours than on its immediate withdrawal. The styptic effect of the metal, as the result of coming in contact with blood, together with the formation of clots and the closing of the opening resulting from the puncture by allowing the weapon to remain, will be amply sufficient in a few cases to prevent a fatal hemorrhage on its withdrawal.

The blood that most resembles in constitution the blood contained in the cavities of the heart is that found in the coronary arteries which, like that in the heart, coagulates with wonderful rapidity.

The blood, after having made the round in the body, comes back to the heart practically exhausted of oxygen. It not only contains CO₂, but other chemical compounds formed by the debris collected uniting with the constituents of the blood. At the same time, it contains more fibrin and doubtless also more of the other elements which add to the coagulability of the blood, for in its course it has taken up the material prepared by the digestion process to repair the wear and tear of the body.

In all cases where important blood vessels were punctured, the observers were impressed by the rapidity of coagulation. It is very probable that Nature has so arranged that in case of trauma where there is hemorrhage of the more important organs, coagulation shall be more rapid than elsewhere, thus preventing death. It seems probable that the rapidity of coagulation is proportionate to the importance of the organ to the animal economy.

Contraction of a lung when the thorax is opened will cause congestion of the heart. The contraction of the lungs, whenever the chest is opened, exerts considerable pressure upon the various pulmonary blood vessels and thus forces a volume of blood, equal to nearly the entire volume of blood normally contained in the lung, into the already engorged heart, thus bringing about a congested condition of this organ.

Care should be taken in operations on the heart, as undue manipulation alone may cause death from paralysis of the vagi.

Opening the Pericardium.—Having checked all hemorrhage from the chest wall incision, and the wound being dry, lift up the pericardium with a tenaculum. Great care must be taken not to puncture the cardiac tissue or coronary artery. The tenaculum should be inserted over the ventricles, as there is danger of wounding the thinner auricular wall.

The incision should be made with its longitudinal diameter and may be extended to any degree necessary to facilitate rapid work and should be done by tearing. Each bleeding vessel must be closed as soon as opened. When the pericardium is incised it retracts, and owing to its thinness is almost lost sight of. It, however, can be replaced and sutured in position with a moderate degree of ease. The pericardium is normally completely filled by the heart, and when the heart is beating and not even restrained by the chest wall, its range of movement is very great. This must be seen to be appreciated.

The pericardial cavity is now cleared of all clots by one sweep of the finger, if possible. Gauze may be carefully wrapped around the finger, but it is best not

to use it. Pericardial adhesions increase danger of operations.

Treatment of the Heart.—The heart is gently grasped in the palm of the left hand, great care being taken not to use any more pressure than is absolutely necessary to enable the needle to be plunged through the wall of the incision.

The heart can be handled to a remarkable degree without any appreciable change in beat, except the dilatation caused by the loss of the supporting sac—the pericardium. This handling of the heart holds good, provided not too greatly prolonged. The loss of support of the chest wall and, more important, the close-fitting pericardium, causes a great extra strain on the myocardium.

Careful inspection of the naked heart shows its great distension, and when it seems or really is paralyzed by over-distension; holding together, for a moment, the wound in the chest wall, will cause the heart to regain its normal action. The operation may now be continued. If necessary, this may be repeated several times during the operation. The heart-operation being finished, it is returned to the pericardial cavity, the pericardium now being brought into position with small tenacula, a running suture of catgut is placed in it.

As the artery tension is not so great when the chest wall is closed, a suture can be used that need not last so long. The pericardium tends to go back in place after the replacement of the heart. There was a plastic pericarditis in all the autopsies, and the pericardium was adherent for a variable distance around the incision in the pericardium, from half to one inch.

In most cases the pericardium was not sutured and the result was very good as to replacement. So good, that in any case in which there is danger in prolonging the operation, one is justified in allowing the pericardium to remain open, for the closing of the wound tends to keep the heart in place and keep the pericardium closed.

Ventricles.—This same work does not so well control the hemorrhage in wound of the left ventricle, as the wall is very strong and resilient; however, this method is the best and most convenient, and it is always easy to govern the degree of pressure, which should be only great enough to prevent blood from coming out during systole, and in diastole the pressure should be slightly relaxed.

As to putting the needle through during systole or diastole, I think that will be forgotten when it comes to the work, as with a heart bounding and changing position at least one-half to one inch seventy to one hundred times a minute, we are glad to get a needle within one-quarter inch of the mark aimed at.

Auricles.—When the right auricle is opened, naturally the blood comes out with considerable force, but this can be entirely controlled by putting the ball of the finger over the opening, yet the force does not have to be great enough to obliterate the auricle or press the walls in contact. The pressure can be accurately gauged in this way, and it controls the hemorrhage almost perfectly.

Suturing the Heart.—This is very essential. Should a needle not be ready, the finger can be kept in place while a well-curved needle is passed from one side to the other under the finger. The needle should be long and a half-circle, but not heavy. Theoretically, to insert the needle in diastole is right, but it is one part of theory that we lose sight of in the critical moment, and should the heart cease to beat for a few seconds to a

minute, or even two minutes, which it does, our duty is to keep the finger on the heart wound and close the wound in the chest by seizing its edges, keeping the finger in position. Then, if the heart resumes its beat, further effort can be made to close; if not, the work is finished anyway.

The question as to whether to continue work even though the heart stops is an open one. On one side we have the very great advantage of a quiet tissue to work on, which will be positively frightening when it comes so suddenly, and on the other the less chance or probable less chance of resuscitation, if we keep the chest open. We should choose the lesser evil if we can sometime decide which really is best.

In suturing the heart tissue the organ should be held as securely as is consistent with minimum pressure and suturing done as rapidly as possible, knots being made by an assistant. Glover's continuous suture is preferable to all others, because fewer and less complicated knots are required. This is especially desirable when silk is used, the object being to get rid of knots by absorption as quickly as possible.

The simple continuous suture without knotting, except in the first and last punctures, would be ideal but for the great danger of the suture breaking, and thus allow reopening of the wound. This is the great danger in using absorbable or non-absorbable material, as they must of necessity be very light. Both silk and kangaroo tendon have been used with great satisfaction in suturing, penetrating and non-penetrating wounds of the heart, also for ligating the coronary arteries at various points. However, the preponderance of evidence is in favor of the interrupted suture, and that it should be twisted silk. Even though kangaroo tendon is more absorbable, wounds of the heart repair themselves as rapidly, if not more so, than other tissues, and the pericardial adhesions are proportionate to the extent of injury, whether clean or infected.

Interrupted sutures should be used, and the needle and silk should be as small as will render service. They should be about one-eighth of an inch apart, and taken deeply into the tissue. If the cavity of the heart has been opened the needle should be made to pass through the entire thickness of the heart's wall. If the endocardium has not been punctured, the needle should be made to traverse the floor of the incision. The strength of the suture material should be determined at the time of operation. Knotting of the sutures should be firmly secured and their respective ends about one-quarter of an inch in length. If shorter, the constant action of the heart may possibly untie them.

Kangaroo tendon has been used in suturing muscular tissue of the heart and ligating the coronary arteries with considerable satisfaction, more especially in ligating the coronary arteries. Its life will depend on the size and quality—the greatest objection being to its size. A large needle is required and the punctures from it must necessarily be larger than when silk is employed. Catgut offers the same objections.

It is pretty well agreed on by experimenters that the sutures should be applied during systolic relaxation, that the cut edges may be perfectly coapted. However, Rhen tied them during diastole with equal success.

It is not necessary to suture or apply any kind of treatment to some wounds of the heart; they will close and recover spontaneously. It is impossible to say or determine the size of wounds necessary to be sutured, or to be let alone, except from continuous bleeding, which can only be determined by opening the chest. It must

necessarily require much time and careful observation of many heart wounds, to determine the necessary procedure in each individual case.

The probabilities are that punctures, however small, into the left ventricle or auricle become enlarged with its systole and that death results sooner or later from hemorrhage alone. Not so, however, with the right ventricle and auricle, the mortality being less with similar wounds. Therefore, one is justified in believing that sutures are less likely to tear out in the thick walls overlying the cavities of the left heart. This statement appears inconsistent. In the more highly developed and older animals of mature ages the heart will be more likely to be sutured successfully.

The superficial vessels (coronary arteries and veins) lie side by side and the amount of hemorrhage in case of trauma depends on its distance from the origin of those vessels. It will depend also upon the character of the wound. Knife and needle wounds, or those of sharp-edged weapons bleed the most and superficial lacerations least.

Closing the Chest Wall.—The closure of the chest of animals is difficult for the reason that the animal can not be kept quiet. Of course, there are several ribs, and at times these are to be closed in two places.

There was silkworm gut and silk (heavy) used in most cases, silk for the bony wall and intercostal muscles, one suture on each side, or rather one between each rib; the ribs were as nearly approximated as possible. Then the muscle and the skin all in one layer sutured with silkworm gut. As before stated, the two tiers of sutures do not come directly above one another, due to the fact that after the first incision was made the outer flap was dissected up for a distance of an inch and then the wall opened. This puts the two rows an inch apart and protects them from the contamination by infection and also makes a sort of valve, like the operation for colotomy and gastrotomy.

In putting in the external sutures they should be close and extend down into the intercostal muscle under the line of skin incision to add to the security of the wound. Not often was there any trouble in getting the wound closed well enough to prevent the passage of air into the pleural cavity.

Drainage and Dressings.—Drainage should be provided for in the same way as wounds in other parts of the body and governed by the same principles. Dressings should be aseptic and securely held in place with adhesive plaster and bandages encircling the body and about the shoulders.

Post-Operative Treatment.—Simple nutritious food should be prescribed with more or less stimulation, as the case may require. Alcohol by the stomach in the absence of nausea. If there is nausea it should be given by the rectum.

Artificial heat should be applied if the temperature become subnormal or if it be otherwise indicated. Oxygen is indicated and is probably the most satisfactory way of stimulating when stimulation is demanded.

RESULTS OF EXPERIMENTS.

In carrying on the series of experiments the object was to induce as many complications as possible. That this might be accomplished aseptic principles were disregarded and the pleural cavity many times entered. In a few instances clots were allowed to remain in the pleural or cardiac sac and sometimes both, that their disposition might be observed. In Case 1, two tablespoonfuls of blood were allowed to escape from the coronary artery into the pericardial sac and there al-

lowed to remain. The clot was afterwards found intact.

Pericardium.—Removal of the pericardium by incision was done in two cases. In one death did not ensue; dissolution occurred in the other (Case 8) as the result of infection, which might have been avoided. In the case of recovery, the heart was adherent to the surrounding tissues. In two cases the pericardium was divided from apex to base with scissors and allowed to retract upon itself, leaving the heart practically in the same condition as if the pericardium had been removed by excision; death resulted in one of these cases.

In Case 5 the pericardium was divided longitudinally and sutured to the chest wall with silk. The animal was killed sixteen days afterward. Even though this dog on the third or fourth day removed these sutures in the chest wall with his teeth, the wound was not infected. He was allowed to lick the wound until the sixteenth day, when he was killed. Autopsy revealed about one ounce of serous fluid in the pleural cavity. There were adhesions of the pleura, pericardium, lungs and heart to one another and to the chest wall.

Coronary Arteries.—It has been found that the ligation of either of the coronary arteries at any point of their distribution will not produce death. In Cases 1 and 9 silk was used for ligation. In Case 3 kangaroo tendon was employed, the ligation being applied at the origin of the artery. The dog's life was taken in the latter case on the fourteenth day and complete repair following the ligation found to have taken place. Several similar experiments were made with the anterior coronary arteries with practically the same results.

Accidental puncture of one or more branches of the coronary arteries occurred in three cases, more or less complicating the operation.

In Case 2 the posterior coronary artery was ligated about midway from apex to base, the second branch being accidentally punctured with the needle was also ligated at the bifurcation of the main branches.

Incisions.—Penetrating and non-penetrating wounds of the heart were made with a bistoury after the chest had been opened and were allowed to remain open from one to ten minutes before closing them with suture. Oblique perforations bleed less, as they are valve-like in character.

In Case 6 two incisions were made in the apex over the left ventricle, each being one-half inch long. The dog died at the end of seventy-two hours. The incisions were estimated to penetrate about one-fourth the thickness of the ventricular wall. They were shown at autopsy to have practically repaired themselves. The dog was found to have general tuberculosis, which was suspected at time of operation and which was, no doubt, the cause of his death, there being no other perceptible cause.

In Case 9, while suturing a penetrating wound three-eighths of an inch long, made in the left ventricle, the left branch of the anterior coronary artery, which had been accidentally punctured, was included in the last and upper suture. The animal died at the end of seventy-two hours. Autopsy revealed about a pint of bloody fluid in the pleural cavity. Also adhesions between the pericardium and chest wall, and between the pericardium and heart. The wound in the heart was completely and permanently closed.

In Case 10 a fine needle armed with silk was made to pass so as to make four sutures closely approximate over the left ventricle, the object being not to perforate the endocardium.

Case 11 demonstrates the suturing of a non-penetrating wound one inch long, involving about half the thickness of the ventricular wall and in which silk was used for suture. Complete suspension of respiration lasted two minutes, but operation was not discontinued during this time. Normal respiration was re-established spontaneously. Death occurred seventy-two hours afterward as result of infection due to the animal having torn out all the sutures in the chest wall. The incision in the heart had firmly united, the heart itself being nearly firm.

In a small non-penetrating wound in Case 14 in the wall of the left ventricle, a continuous suture of silk was applied. Respiration ceased, as the pericardium was being opened, but soon re-established itself and again ceased upon completion of the last stitch. It was not again re-established. The heart continued to beat for two minutes after the last respiration. If death had resulted from the puncture of one or more cardiac ganglia, the heart would not have continued to beat for two minutes after the last respiration.

In Case 17 death occurred while incision was being made in the left ventricular wall. This may have been due to injury to one or more of the automatic ganglia. This is hardly probable; at least, it has not been proven because death has occurred under similar circumstances without any injury to the heart.

An incision requiring two silk sutures was made in the wall of the left ventricle in Case 18. These sutures were made too tight and therefore cut through the muscular tissues of the heart, resulting in death.

Needle Puncture.—One or more punctures of the heart were made in several cases in various portions of the heart. In one, eighteen such punctures were made in various portions of the heart, from the apex to base, the object being to injure the cardiac ganglia. In no instance did death ensue, nor were the movements of the heart influenced to any noticeable degree.

Cardiac Stimulation.—Stimulation of the heart to action after it has ceased was accomplished several times by rhythmically compressing the apex of the heart with the fingers, also by pricking the apex of the heart with a needle.

The most interesting of all such experiments was in Case 16, in which a non-penetrating incision was made in the left external ventricular wall, necessitating the introduction of four silk sutures to close it.

CASE 16.—Aug. 21, 1901. Very fat, black mongrel, age 4 years, weight 50 pounds. Chest cavity opened and pericardium divided. An incision one-half inch long was made in the external wall of the left ventricle; incision in heart's wall closed with four sutures of silk. At this stage of the operation respiration ceased. Muzzle was taken off. Cone for applying anesthetic had been withdrawn about the time the operator began to suture. The operator held the opening in the chest cavity closed with both hands; an assistant kneaded the abdomen in an effort to restore respiration. At the end of the first minute the operator introduced one hand into the thoracic cavity, still holding the chest opening closed with the other hand, and stimulated the heart by pinching the apex. After a time the dog took a deep, labored inspiration. Then respiration was suspended again. Again a few deep, labored inspirations; then suspension for a considerable interval. This procedure continued for several minutes. There would be several deep, labored inspirations at comparatively short intervals of time; then inspirations would be single with a longer interval of time between each inspiration; then a series of labored respirations at shorter intervals of time between each inspiration.

This alternation of single, deep, labored inspiration at considerable intervals followed by a series of several inspirations

not quite so labored, and at shorter intervals between each inspiration continued until the dog regained normal respiration. The operator, in stimulating the dog's heart, observed and called the attention of his assistants to it, also that the heart began beating at the end of each inspiration. There were three beats of the heart after each inspiration. The movements of the heart ceased with the suspension of respiration. After each labored inspiration the heart would beat three times, but would be absolutely motionless in the interval between inspirations. The heart's movements were completely suspended $3\frac{1}{4}$ minutes. Respiration was suspended this length of time, and the heart did not beat until after the first inspiration. It took about three minutes after the first deep, labored inspiration for the dog to regain normal inspiration.

In no case when suspension of respiration occurred in this series of experiments were drugs given subcutaneously or otherwise to promote the heart's action. Neither was resort made to transfusion or any other artificial means employed to stimulate the heart.

Autopsy.—Dog died August 29, and postmortem was made the same day. Infection general; a quart of bloody fluid in pleural cavity; sutures in both the chest wall and cutaneous structures had rotted away. Pericardium, heart, pleura and lung were adherent to one another and to the chest wall.

ADDRESS ON AN EXHIBIT OF EARLY (PRIOR TO 1860) BRITISH AND AMERICAN OPHTHALMIC LITERATURE.

CASEY A. WOOD, M.D.

CHICAGO.

(Concluded from page 1156.)

Two years after the publication in Philadelphia of Saunderson's work, there appeared the first text-book by an American writer, George Frick. We owe most of our knowledge of this pioneer of American ophthalmology to our distinguished colleague, Harry Friedenwald. I quote from his interesting contribution to the *Johns Hopkins Hospital Bulletin* for August-September, 1897, "The Early History of Ophthalmology and Otology in Baltimore."

Frick was born in Baltimore in 1793. After obtaining a broad classical education he entered the University of Pennsylvania, where he obtained the degree of doctor of medicine in 1815, and in 1817 he was admitted as licentiate of medicine into the Medical and Chirurgical Faculty of Maryland. He then spent several years abroad, returning to Baltimore about 1819 to engage in the practice of ophthalmology. He was appointed surgeon to the Baltimore General Dispensary, where he established the first Eye Dispensary in Baltimore, in 1824. In 1832 he delivered clinical lectures at the Maryland Hospital. His name is found on the list of vaccine physicians for 1821. He was a member of various medical societies; was secretary of the Faculty in 1823, and joined the Maryland Medical Society in 1822. He was much interested in general science, and was one of four physicians to organize a society for promoting science in 1819. He was likewise a member of the Maryland Academy of Sciences, its librarian in 1824 and curator in 1836. He devoted himself to the practice of ophthalmology and to the cultivation of general scientific studies, as well as to music for a number of years. He was unfortunate in growing very deaf before middle life, and it is probable that this interfered greatly with his practice in medicine; for somewhere about 1840 he entirely relinquished it and left Baltimore to spend most of his time in Europe, paying occasional visits to this country. He died in Dresden, March 26, 1870, aged 77 years. Dr. Frick had never married. He was a man of very retiring and modest character and of kind disposition. He was a careful scientific student and his work and writings deserve high praise. In 1820-21 his article on "Observations on Cataract and the various modes of operating for its cure"

appeared in the *American Medical Recorder* of Philadelphia. In 1821 an article on "Observation of the various forms of Conjunctivitis" appeared in the same journal, and in 1823 his paper on "Observation on Artificial Pupil and the modes of operating for its cure." His most important work, however, was "A Treatise on the Diseases of the Eye; including the doctrines and practice of the most eminent modern surgeons and particularly those of Professor Beer," which was published in Baltimore by Fielding Lucas, Jr., in 1823. It was inscribed to his teacher, Dr. Physick of Philadelphia. It is well and clearly written, the system on which it is classified is excellent, and no greater praise could be given it than stating the fact that it was republished three years later in London by an English surgeon, Richard Welbank, a member of the Royal College of Surgeons and of the Medical and Chirurgical Society of London, and dedicated to the ophthalmologist, William Lawrence. Numerous foot notes were added, but the text suffered no change. The reviews which the book received were very complimentary. The *Philadelphia Journal of Medical and Physical Sciences* (probably Dr. Isaac Hays) contains a review covering 18 pages: "The author evidently possesses a cultivated and well-disciplined mind; he appears to be intimately familiar with German writers, and we feel much indebted to him for making us acquainted with their writings."

In the *American Medical Recorder* of 1824 a still longer review is to be found, covering 32 pages. The writer describes the book in terms of high praise. He "offers the humble tribute of (his) thanks to the author for the benefits which he has conferred on the profession generally, by presenting them with a volume of great value and utility, and one which was much wanted. As a manual of the diseases of the eye, we believe it to be the best which has been published. It contains all the improvements which have enriched ophthalmic surgery, in such a surprising degree within a few years past," etc.

In 1825 this work was placed on the list of those which the student was required to have read before applying to the Medical and Chirurgical Faculty of Maryland for the examination for licentiate in medicine.

While we are on this subject let me remind you that Frick's was not the only early ophthalmic treatise written by an American and republished in London. Littell's "Manual of Diseases of the Eye," first printed in Philadelphia thirteen years after Frick's treatise saw the light, appeared in London two years later (1838), revised and enlarged by Hugh Houston. The preface to the first edition, which was a very creditable performance, exhibits, however, an astounding ignorance of contemporary literature. The author had never heard of his compatriot, Frick, and I suspect was equally ignorant of the writings of several of his predecessors. For example, he says nothing about a compilation, published in 1832 by W. R. Lucas, of John Mason Gibson, who, like Frick, was a member of the Baltimore school. Friedenwald says of Gibson:

He was admitted into the Faculty in 1825, and that his name appears as late as 1848 in the list of members with the title of L.M. In the next succeeding list published in 1853 Gibson's name is missing. In the preface he tells us that his book is an "attempt at collecting the best matter on diseases of the eye"; that "diseases casual to vision are many and frequently met with in this country; the curative practice has not been sufficiently inculcated in our universities, by impressing on the mind of the student where and when the importance and great nicety of judgment are requisite in the treatment of them, and that by inadvertent and malpractice the victim may grope through his existence here in the valley of darkness." The work is one of compilation, "being made up of extensive quotations from the classical writers of the day." He claims originality only in the construction of his plates, and so far he is certainly correct, for the drawings are quite unlike anything seen in Nature. The arrangement of the work is very curious. The chapters follow in this order:

Anatomy of the eyeball, cataract, ophthalmia, corneitis, iritis, choroiditis, retinitis, inflammation of the lens and its capsule, ulcers of the cornea, opacities of the cornea, pterygium, prolapse of the iris, extirpation of the eyeball, extraneous bodies, diseases of the lachrymal apparatus, under which is included entropium, ectropium, epiphora, encanthus, injury of lids, ophthalmia tarsi and fistula lachrymalis, looking very much as though the subjects had been drawn haphazard from a grab-bag. At the end of several chapters the author adds original remarks. When we consider the very excellent and systematic work which Frick had published, nine years previously, as well as such other works from which copious quotations are made, it is quite inexplicable why Gibson showed such disregard of systematic classification, or indeed what purpose he had in publishing the work at all.

I can not let this opportunity pass without a reference to the fact that Americans early began to push forward the car of ophthalmic progress. In a recent review of this subject I pointed out (what was known in a general way) that Isaac Hays, the first editor of the *American Journal of the Medical Sciences*, was, as well, a voluminous writer on ophthalmic subjects in the still earlier *Philadelphia Journal of the Medical and Physical Sciences*. He was the inventor of the knife-needle, pictured in Bull's edition of Solberg-Wells' "Treatise on the Eye" (page 339, 1855). In the former journal for November, 1831, will be found one of the earliest accounts, by H. Morton, of the relations of convergence to accommodation. Again, in the same periodical, for April, 1845, Earle has written an original essay on "Color Blindness." If John Taylor did not do the first operation for strabismus it is highly probable that the idea was carried into practice by at least two Americans years before Stromeyer and Diefenbach published their monographs. Here is the evidence, which you may accept for what it is worth: Atwell, writing in the *Philadelphia Medical Examiner* for February, 1842, says: "In the year 1812-13 I attended courses of surgical and anatomic lectures delivered before the medical school of Brown University by William Ingalls, then the professor of anatomy and surgery in that institute; being subject myself to this infirmity (strabismus) Dr. Ingalls took frequent opportunities to explain to me the method of its surgical cure—he did this by dissection of the eye itself—giving an explanation of the power and disposition of the several muscles appertaining to that organ, and showed me how by a division of one or more of them the eye might be brought to its proper place. In my own case I know he proposed to divide the rectus internus. So strongly was I impressed with the practicability and success of this operation that I strongly urged my father to permit me to submit to the operation; but upon the nature of the operation being explained to him he declined the permission because he feared the effect might be to turn the eye the other way."

If this be considered insufficient grounds for awarding the claim of priority of discovery, I quote from Friedenwald's history as follows:

In the American Appendix to the second edition of Cooper's "Dictionary of Practical Surgery," edited in America in 1844 by David Meredith Reese, who in 1842 was professor in Washington University of Baltimore, we find a very curious reference to Professor Gibson under the head of strabismus: "It appears from the Institutes of Surgery that Professor Gibson attempted the cure of strabismus by dividing the recti muscles of the eye, precisely as now practiced, some twenty years since, in Baltimore. Soon after he repeated it unsuccessfully in Philadelphia, in several cases, and was induced to abandon it by unfavorable opinions expressed on the operation by Dr.

Physick. He, however, inculcated the propriety of the operation on his class many years since, and Dr. A. E. Hosack of New York, then one of his pupils, distinctly recollects Dr. Gibson's expressions of confidence that the operation would ultimately succeed. I had no little difficulty in finding the reference to which Dr. Reese refers. The first five editions of Gibson's *Institutes of Surgery* (published between 1824 and 1838) contain no chapter devoted to strabismus. Its treatment consists almost entirely in a paper written by Charles Bell and sent by him to Gibson. In this chapter the above reference is likewise not to be found. It is only in the sixth edition, published in 1841, that we find the reference. It is of such importance that I shall give it in detail. On page 375 Gibson states that: "In the year 1818, while practicing my profession extensively in Baltimore, the late Mr. B. J. consulted me about his daughter, a child of eleven or twelve years of age, both of whose eyes were directed very much inwards, and were thereby greatly deformed by a squint. I advised a pair of goggles, so contrived by having a small opening in the center of each, as to oblige the child to direct the cornea to these openings, and by perseverance for several weeks, succeeded in diminishing the deformity but not effecting a cure. In the course of my visits the child remarked at different times that her eyes felt as if tied by a string. Struck with this observation, and conceiving the disease might depend on shortening of the internal rectus muscle, I determined, the first opportunity, to try the result of division of that muscle; and as the friends of my young patient were unwilling the experiment should be first tried on her, I selected a hospital patient, and after some difficulty in fixing the eyeball and cutting the muscle across, succeeded in restoring the eye partially to its natural situation. On two other patients I repeated the experiment, without much better success, but on dividing a muscle in a fourth patient, after my removal to Philadelphia, the eye was so completely turned to the opposite direction as to bury the cornea beneath the lids and create a much greater deformity than had previously existed. On showing the patient to Dr. Physick, he advised the experiments to be abandoned, as likely to be followed by very unfavorable results. I mention these circumstances, not from a desire to receive credit as an inventor or to detract from the claims of the distinguished surgeon with whom the modern operation of strabismus originated, but merely as a curious fact, calculating to show the importance of not laying aside processes apparently founded on correct principles, simply because we are at first foiled in our attempts to execute them. How much benefit would have resulted to the community if I had followed up my operations until I ascertained the proper mode of correcting them, or how much injury I might have inflicted on individuals by perseverance in the attempt; I shall not stop to inquire. It is sufficient for me to announce the fact—which I have no doubt could be easily substantiated by many pupils who attended my early lectures, some of whom have indeed already proffered their testimony—without being over-solicitous, in setting up a claim as an inventor, of exposing my awkwardness and perhaps want of knowledge of the principles that should have guided me in following out the practice I had attempted to institute.

The Professor Gibson referred to is William Gibson, born in Baltimore in 1784, educated in Edinburgh, professor of surgery in the University of Maryland from 1812 to 1819, and in the University of Pennsylvania from 1819 to 1854. Besides this claim of the discovery of the operation for strabismus, Hirsch tells us that Gibson described as early as 1819 (see the *New England Journal of Medicine* for that year) the following original operation for the removal of cataract:

The iris was in the first place dilated by the application of atropa belladonna. A common sewing needle, slightly curved and armed with a single thread of silk, was then passed through the tunica sclerotica about two lines from the cornea where the couching needle is usually introduced, through the opaque lens and out of the opposite side of the cornea, at a point corresponding to the one at which it was introduced.

The silk being drawn through, and the ends cut off, a single thread was just left passing through the ball of the eye, and acting on the diseased lens in the manner of a seton. It was feared that serious inconvenience might arise from the irritation produced on the tunica conjunctiva from the excessive sensibility of this membrane. Fortunately, however, neither this nor any other accident intervened, and at the end of ten days, in both cases, the diseased lens had disappeared, and in its place the silk was distinctly seen passing like a bar across the pupil of the eye. The silk was withdrawn and in a few days the vision was restored. In the third and last case in which this operation was performed it failed, in consequence of the iris being wounded. This caused such an inflammation of the organ that it was deemed proper to withdraw the seton at a very early period. This accident was attributed to not using the belladonna.

Roosa in his text-book calls attention to the fact that Professor Dewey of Union College (1849) has a strong claim to the recognition as the discoverer—prior to Donders—of hypermetropia and called by him neomacropia. Blackman's operation for the relief of spasmotic entropion, said to be superior to Himly's, is described in the *New York Lancet* for June, 1842.

The first periodical printed in English and devoted to the eye and its diseases is the *Royal London Ophthalmic Hospital Reports*, the first number appearing in 1857. Five years afterward (in 1862) the second one, the *American Journal of Ophthalmology*, edited by Julius Homberger and published in New York, survived two years.

This list of American publications containing original discoveries would be incomplete if no reference were made to the first Canadian treatise on the eye, a work of 517 pages, edited by Henry Howard of Montreal, in 1850. In it, among other interesting matter, will be found an illustrated description of the author's method of removing cataract with an "arrow-head" knife.

It seems strange that the invention of the ophthalmoscope should have produced so few English and American atlases reproducing fundus findings. The early maps and atlases of Wardrop and Dalrymple, reproducing mostly external diseases of the eye, furnish numerous and beautiful examples of the engraver's art, wrought in a style that puts to shame many a more pretentious volume of recent years. If we stretch a point and except a small and badly made book by the British ophthalmologist, Jabez Hogg, issued in 1862, no English atlas falls within the time limit of this paper.

One of the most marked and beneficent literary results of the use of the ophthalmoscope was to greatly abbreviate the long vocabulary and to restrict the nomenclature of ophthalmology, generally because the many so-called functional diseases were shown to be due to demonstrable lesions, and many so-called diseases were found to be symptoms merely, often of several widely differing lesions. The long-winded chapters and monographs on "amaurosis and amaurotic affections" practically disappear from literature. Ophthalmologists were able to smile with Walther, who described the amaurosis of the pre-ophthalmoscopic era as a condition in which "both the physician and the patient were blind."

May I, in closing, draw your attention to the excellencies of William Mackenzie's text-book (1833-1855). Let us take, for example, the edition containing addenda; notes by Addinell Hewson and the Wharton-Jones prefix—the second American edition—published in Philadelphia, 1855. I do not believe that there is to-day, in any treatise, a better account, from a clinical standpoint,

of the ordinary external diseases of the eye. The two decades of Mackenzie's activity bred a school of clinicians whose like, having in mind their necessary limitations, we have not so far seen and may never see again. In a sense—a narrow sense perhaps—the introduction of objective means of examination seems to be coeval with a diminution in our powers of observation. The lessons to be learned by simple inspection of the eye and of the patient, as well as by the careful weighing of the evidence afforded by his symptoms we have exchanged for such signs as are demonstrable by the ophthalmometer, the microscope, the ophthalmoscope, the retinoscope and the use of magnifying glasses with the oblique and other forms of examination. Far be it from me to underrate the value of these means of diagnosis; I merely wish to point out that the text-books of half a century ago were, in the main, characterized by what seems to me to be lacking in modern treatises—a proper regard for the purely clinical aspects of ocular disease.

Another fact that must strike the reader of the best of the mid-century treatises is that if a fairly large percentage of the population now consult the optician instead of the ophthalmologist the profession is pretty much to blame for the practice. This, for example, is what Mackenzie says: "When a near-sighted person wishes to be fitted with concave glasses, the simplest and surest plan is to try a series of them, at an optician's shop"—and, sure enough, the short-sighted person has continued to "try a series" ever since!

One might multiply indefinitely the observations which every reader of the writings of the fathers in ophthalmology would be likely to make. They do not differ, let us hope, from the acknowledgments which our children's children will make of our patient strivings after truth, of our undoubted accomplishments and of our hopes for the future, nor can we hope to escape at the same hands criticism of our primitive methods, our mistaken pathology and our ineffectual therapeutics.

BIBLIOGRAPHY.

[Unless special acknowledgment is made of another source, the books in the exhibit were contributed, in about equal proportion, by members of the Committee, from their private libraries.]

RENAL INSUFFICIENCY IN THE TROPICS.*

JAMES CABELL MINOR, M.D.

Major Surgeon, U. S. Volunteers, Commanding Division Hospital, Los Banos, P. I.; Sanitary Inspector, Headquarters Division of the Philippines, Manila, P. I.

HOT SPRINGS, ARK.

Without touching on the theories of Garrod and Latham on the one side and Haig and his followers on the other as to the origin, effect and disposition of uric acid, which theories prove ever debatable, the writer of this paper passes to the more simple and practical consideration of a certain condition of the blood which conclusively announces the fact that the kidneys are not performing their function and that the condition is one of danger. For the purposes of this essay the cause of "this certain condition" will be referred to as "urinary solids."

Renal insufficiency is failure on the part of the kidney to perform its function. A more practical title to this paper would be, a plea for systematic instruction in the use of water in the tropics. Lack of volume to the circulation means renal insufficiency sooner or later, whether the failure in function on the part of the kidneys be from overwork or from inactivity. Physiologists, writers on practice of medicine, military hygiene and on diseases of the tropics agree that water is an essential proximate principle, and that the normal animated being requires in its economy water in the proportion of 75 per cent. of the bodily weight in order to maintain health, but no one of the writers has offered an emphatic word or a practical word of counsel as to how much, when or how water should be consumed so as to properly and faithfully discharge the function of maintaining bodily health.

It can not be assumed that all who thirst will drink; this is true only of the lower animals who are guided instinctively to self-preservation, and true only of those of the higher class of animal, man, who have recognized the importance of obeying nature's calls rather than sacrifice the benefits to be derived from her wisdom, to pleasures and to the seeming necessities of life's vocations. The business man is on guard as to his stock in trade; the worry from watching employes and his other anxieties of the busy forenoon crowd back into insignificance nature's appeal for water at regular intervals. Not until the fever heat in the throbbing heart of finance has cooled from its daily rise does the man on 'change listen to the call for water to supply the waste incident to the rapid combustion that has taken place; water to

flush the channels of the debris of conflagration. The farmer building his fence, digging his ditch or plowing his crop is too much absorbed in visions of prosperity and air castles to stop now and then to replace the loss sustained by sweating; he will stagger a while longer under his burden, it will soon be noon and then he can drink with unlimited satisfaction from the old well. All procrastinate when the instinctive call for water appeals to them, and each readily puts it off to a more convenient season, which will be, usually, the next meal hour, then each takes more water than is wholesome, either for the digestive process or for nerve functions. These classes have not been taught.

When the instinctive call for water appeals to the soldier he would probably respond, but under present discipline he is forbidden. No attempt is essayed here to criticise, but attention is simply invited to the fact that there exists among those on whom the army unit depends for sanitary instruction an almost decided trend warning the soldier to leave water alone as a dangerous element in the camp and field; simultaneously, the same men may write chapter after chapter on the important theories of obtaining pure water, but never a line as to how much of it to drink, or when or how. One writer on military hygiene advocates "the habit of rarely drinking between meals" (Munson), and further on in his magnificent work mentions gastro-intestinal disorders due to drinking water at meals. Official documentary hygienic guides direct the soldier to "drink as little as possible even of cold water." They say: "Experience teaches the old soldiers that the less they drink on the march the better, and that they suffer less in the end by controlling the desire to drink, however urgent." There is no reason given for this advice except that "Experience teaches the old soldier." If the soldier can not drink water in safety between meals, or at meals, or on the march, what must he drink, and when must he drink, now that the canteens are closed?

The score of authors on military hygiene and on tropical disorders appealed to on this subject, either by silence or by feeble assent confirm in a measure the water abstinence dogma. Only one writer encountered lays stress on the importance of keeping the system supplied with water as fast as it is dissipated. Colonel Smart, in his paragraph on sunstroke, advises the halting of troops on the march every hour in order to re-adjust equipment and replenish water supply. If this eminent authority so advises for troops in the temperate climates, how much more important for obvious reasons are frequent halts on the march for troops in the tropics. The field and line officers of the old "establishment" are familiar with the old dogma, and many of them here in the tropics insist on punishing themselves and the men with thirst and its sequels.

Since pitching camp on La Loma line in the fall of 1899, and on for two years in the field in the provinces of Union, Benguet, Laguna, Morong and the islands of Romblon, Tablas and Samar, attention has been drawn to a heterogeneous accumulation of symptoms among the sick that could indicate no other disorder than auto-intoxication from renal insufficiency, faulty assimilation of food playing its part. The daily exhausting practice marches for green troops, the reconnaissances, the expeditions and the fatigue work to which the men were subjected in steaming jungles, rice fields and mountain trails, together with their negligence, ignorance or fear, from one cause or another, of the drinking of water, would invariably yield to the field hospital a daily contingent of disorders which would seem not so much at-

* Read before the U. S. Army Medical Lyceum, Manila, P. I., March 11, 1902, and contributed for publication by permission of the Chief Surgeon, Division of the Philippines.

tributable to the popular adversary "malaria" in its several phases and other alleged ailments as primarily due to auto-intoxication from renal insufficiency. Men on days following such exhausting duties would present themselves, inviting attention to some of the following disorders: rheumatism, fevers, cardiac disturbances, headaches, urethritis, non-specific and recurrent specific, cystitis, skin eruptions (suddenly appearing and later developing into classified dermatia, many with glandular and suppurative complications), melancholia, nostalgia, hysteria, neuralgia and well-defined dementia.

According to Munson, Manson, Moore, Nielley, Cullimore, Rattray, etc., the disorders for which the tropical climate seems responsible (excepting infectious or endemic diseases) are as follows, and in fact no other than those mentioned above, the symptoms of which can be shown to be those of uremia due to excessive loss of body fluids by the skin or to consequent suppression of the excretion of urinary solids.

1. *Nervous Disorders*.—Insomnia, somnambulism, irritability of temper, inability to concentrate thought, neuralgia, hysteria, dementia, etc., and the nerve suffering from what Dana calls "nerve desiccation" acute.

2. *Gastro-Intestinal Disorders*.—Dr. Munson says, due to "great loss of bodily weight by sweating" there is "diminution of saliva, mucus, gastric biliary and pancreatic juices; dryness of the throat and fauces, exaggeration of thirst, weakness of appetite, impaired digestion, gastric fulness after eating and habitual constipation." What more urgent appeal is needed for water?

3. *Cardio-Vascular Symptoms*.—Quoting from the same writer, "there is low heart beat, lowered arterial tension, due to loss of fluids by increased perspiration favored by relaxed capillaries."

4. *Cutaneous Eruptions*.—To what extent the skin is capable of excreting urinary solids is a moot question, but clinical observation would indicate that its power in this direction is by no means compensatory for the inactivity of the kidneys in the tropics. The skin in its unbridled effort to throw off effete material becomes excrement-sodden, so to speak, and in this irritated condition makes a favorable nidus for parasitic and other enemies of the skin. Bulkley has discussed renal insufficiency in its relation to skin affections and no further mention is deemed of need here.

5. *Genito-Urinary Disorders*.—Due to the "enormous amount of sweat, often amounting to four or five pounds a day—scanty, high-colored and highly acid urine" (Munson). Dr. Munson notes as the result of increased perspiration in the tropics the diminished amount of urine excreted as being one-third only of the usual amount in the temperate climates. He quotes Mourson and Eijkman as to the diminished amount of urinary solids excreted, but no particular stress is laid on the prevention of the effect this irregularity may have on the system in producing or exaggerating any of the disorders for which the tropics are peculiar.

In April, 1900, out of two companies in a three-day expedition from Paete east, in Laguna Province, through jungles, marshes and hills, thirty-seven of the one hundred and eighty men who had become hardened and well disciplined by three months of campaigning in the mountains of Union and Benguet provinces, were rendered non-effective in a seven-mile march on the last day of the expedition with the following disabilities: "Melancholia, hysteria, painful and scanty micturition, severe headaches, acute rheumatism and fever, 30; sprained

ankles, 3; gastro-intestinal disorders, 4. (From field diary.)

Six of the thirty had a return of an erstwhile quiescent gonorrhea, and two exhibited a non-specific urethritis. The march was a forced one, and the men were specially denied the privilege of halting for water more than twice in the six-hour march, it being deemed by the commanding officer a breach of a time-honored custom to drink water while on the march.

In May, 1900, a stalwart private of "E" Company, 29th U. S. V. Infantry, after having done an unusually fatiguing tour of guard duty one day in the broiling and steaming streets of Navotas, went to bed early that night, and later, jumping up screaming in his sleep, rushed the length of the barracks and hurled himself through the window to the stone floor below, sustaining a compound complicated fracture of the left elbow. On the morning after the accident, before leaving for Manila, he stated that he recently noticed no ailment save scanty and painful urination. He died of "gas bacillus" poisoning in Manila.

Lieutenant —, U. S. Army, a faithful disciple of the water abstinence dogma, an energetic, untiring and persistent pursuer of the warrior class of Filipino, reports that in last June in an unusually fatiguing forced march, he suddenly became nauseated by pain in the left testicle, became dizzy and unable to march. The following morning a well-defined urethral discharge was present accompanied by an enlarged and painful testicle. The surgeon on duty pronounced the trouble a specific one. The officer had never contracted a venereal disease and so applied for treatment in Manila. The laboratory examination revealed a non-specific urethritis. A well-developed hydrocele is the present sequel. There can be little question that the cause of such disturbances is no other than loss of body fluids from excessive perspiration, the exciting cause being uremia or renal insufficiency.

Up to last April no facilities were offered the writer for making urinary analyses. At the Division Hospital at Los Banos (Hot Springs) ample opportunity and material have been afforded for investigation and for concluding that the many noted cases encountered in the field simulating phases of malaria, heatstroke, rheumatism, etc., were primarily caused by renal insufficiency. The first one hundred cases admitted to the hospital at Los Banos were taken to test the difference in the amount of urinary solids excreted in the Philippines and that excreted in the temperate climates in the same body weight. In the following one hundred cases only one was found to exhibit true casts in the urine:

Number of patients.	Weight.	Total solids; grs. Normal.	Smallest amount of solids passed in 24 hr.; grs.		Greatest amount of solids passed in 24 hr.; grs.	
			On admission.	On return to duty.	On admission.	On return to duty.
3	120	974	145	560	462	806
56	130	1028	156	660	701	1000
20	140	1078	415	665	739	1020
15	150	1150	209	760	957	1050
5	160	1198	363	960	1089	1120
1	170	1237	900	1200		1200
1	200	1330	1023	1270		1270
Average	167	1142	458	865	753	1063

The cases were chronic forms of rheumatism, venereal diseases, skin diseases and neuroses. The results in the above table show a remarkably low excretion of solids on admission to the hospital, and this, too, while the patients were in a passive condition, more favorable for

renal activity. The increase of solids excreted on return to duty commends the idea of systematic instruction in the use of water, for no other treatment was employed.

The sum of the symptoms of the above classified disorders due to meteorologic or tropical peculiarities is equal to or identical with the sum of the symptoms of the gout and uremia of the text-books, and these symptoms are but those of auto-intoxication due to renal insufficiency, with or without structural change in the kidney. Faulty assimilation playing its part.

Garrod, Luff, Latham and others with one theory, and Haig, Bouchard, Jelks, Bulkley and others with another theory, have written at length and in detail of the multifarious annoyances of renal insufficiency, its relation to diseases of the skin, gastro-intestinal disorders, nervous phenomena, cardio-vascular symptoms with and without structural change, and, although they do not come out distinctly and declare the highly important value of systematic use of water, one can plainly see that it is deemed by them the "sheet-anchor" in prophylaxis and in treatment. In the one hundred cases cited, as having been observed in the Hot Springs Hospital at Los Banos, no other diuretic than water was employed; for, indeed, no other was needed to bring about the almost normal excretion of urinary solids, noted on the return to duty of the patients. It should here be explained that the judicious use of hot baths and vapors in this connection in no way impeded the activity of the kidneys. On the contrary, the hot saline water on account of being rapidly assimilated when taken internally, and on account of its benign and certain action on the nervous system by the centripetal pathways, when applied externally, caused an equilibration in the circulation and an almost normal renal emunction.

It is not the purpose of this paper to offer a plan of instruction in the use of water for the prevention and treatment of diseases, although the writer has decided views on the subject. If attention is attracted to the importance of such a plan the object of the paper has been accomplished. There can be no doubt in the minds of surgeons who have served with troops in the exhausting climate of the Philippines that from a practical standpoint much suffering and sickness on the march and following the march can be averted by a regulated and uniform use of water internally and externally. The regulation of such uses of water in the field and in camp can be made practicable. The experience of the writer with the soldier in the field and in garrison inclines him to believe that the enlisted man who takes any interest whatever in being a soldier is never slow to take common-sense advice to the letter when it concerns his diet, clothing, general personal welfare, etc. The enlisted man pays little heed to advice or directions given in a generalizing way. He is neither impressed nor interested. Advice to him must be kindly persistent, special and to the point. Line officers approached on the subject say that it is doubtful whether soldiers can be taught to use water in any systematic way. Why not? The gawky woodsman, the shambling farmer lad and the Bowery "slummer" are, by discipline, gymnastics, foot and arm manual, and the fear of the guard-house, readily transformed into soldiers with grace and action; are made proficient in the care of their clothing and persons, are made proficient in first aid to the sick and wounded; they are taught how to sleep and how to eat; why can not they be taught how to drink water for health? Line officers say that they have watched soldiers here in the Philippines on the march and have observed that those who drank water were invariably the first to

"fall out"; that those who drank water wanted to drink all the time; that the more they would drink, the more they would sweat; that they have seen them approach a well or stream and drink cupful after cupful and fall with cramps and be unable to proceed, thus proving an impediment of serious nature. So has the writer seen just such exhibitions on several occasions; he is making now a plea for instruction of those who do not know.

CONCLUSIONS.

1. Whether the systemic disturbance causing the usual disorders peculiar to the tropics be uric acid or faulty metabolism, or both, the kidneys in the tropics do not perform their share of the work of emunction.

2. The reason for this renal insufficiency in the tropics is that the tide of water (the necessary solvent vehicle for urinary solids) pours through the skin so rapidly that the volume of circulation is so correspondingly diminished that waste products are stranded in those tissues most favored by the weakened flushing force for stasis.

3. The remedy is the internal use of water as fast or faster than it is wasted by the skin in order to force the kidneys to work and to maintain normal volume in circulation, and the external use of water and sun baths systematically for their toughening and contractile influence on the skin.

Clinical Report.

A RARE CASE OF INSANITY.

F. F. YOUNG, B.S., M.D., M.E.
ABBEVILLE, LA.

A year ago there came under my observation a case which I think of sufficient interest to report. It was that of a woman pregnant two months, the mother of three children, all living and in perfect health. Up to this time she had always been well. To all appearances her case the first days resembled a typical case of hysteria, but in a few days it was easily recognized as a case of dementia. As gestation increased so did the insanity. In the latter months she passed almost into a condition of stupor, talking to no one, refusing all food and did not even take care of her person; in fact, she had to be cared for as though a baby. She presented a pitiable sight and became very much emaciated. Labor came on at the usual time and was accompanied by hydrops amnii and complete uterine inertia. The usual oxytocics had no effect whatever.

I delivered her with forceps of a seven-pound boy, perfect in every way. After delivery I gave her no more medication. She made an uneventful and rapid recovery and at this writing is in perfect health. At no time during the disease did she become violent. All medicines usually used for such cases proved futile.

I have seen several cases of puerperal mania occurring after confinement, but this is the first one under my observation coming on at such an early period of pregnancy, lasting so long and terminating so favorably. The urine was repeatedly examined and was found normal; as were also the heart and other organs.

Summarized Conclusions of Original Articles.—The Italian *Riforma Medica* publishes as standing matter on the cover an urgent appeal to authors of original articles to summarize their final conclusions as "useful to the reader and adapting the article for easy diffusion in other periodicals." THE JOURNAL has always advocated this principle, and rejoices to see that it is becoming more universal. A model in this respect is the *Rivista di Freniatria*, also an Italian publication, which not only gives the final summary but has each division of the subject summarized in numbered conclusions before reaching the final ones. Certain German quarterlies also follow this custom. An article thus summarized is easily reviewed and abstracted, and the exact ideas of the writer are comprehended at a glance, and are worthily presented in the brief abstract.

OPERATION FOR CHRONIC NEPHRITIS.

During the past year there has been a great deal of interest in this subject, particularly since the appearance of Edebohls' paper,¹ in which he claimed eight complete recoveries from various forms of chronic Bright's disease at least one year after decortication of the kidney. After report of such brilliant results several operators undertook the procedure, but with less satisfactory results than Edebohls reported. It seems certain, however, that operative measures relieve or cure certain cases of nephritis, and it is a highly important question to determine just what classes of cases are suited for intervention.

From a careful study of a series of 17 cases which he has operated on for various forms of chronic nephritis, Rovsing,² professor of surgery in the University of Copenhagen, attempts to formulate some rules as to the proper treatment in such cases. He divides the cases into aseptic and infectious nephritis. In the aseptic cases he found that diffuse parenchymatous nephritis was not influenced by operation. A case which he classed as chronic glomerulo-nephritis recovered after operation, he believes, more from rest in bed than from any favorable result from the operation. In diffuse hemorrhagic nephritis there is much danger in operating and the results are not satisfactory. In four cases of interstitial nephritis and perinephritis fibrosa occurring with uric acid and oxalic acid diatheses his results were satisfactory. Operation is frequently undertaken with a diagnosis of stone in the kidney in such cases and gives relief without any stone being found. The severe pains which are present in these conditions he believes indicate operation. Pain always indicates tension within the kidney capsule, it does not matter what form of nephritis exists. But the most important group of cases is that caused by some form of infection. Eight of his cases were of this character and the condition was only discovered after most painstaking examination. Urine obtained under aseptic precautions should be accurately examined; chemically, microscopically and bacteriologically in every case, whether we suspect that we have to deal with an infection or not. In case pathologic constituents are found, cystoscopy and catheterization of the ureters should be employed. In his cases Rovsing found infections of the urine from the *Staphylococcus aureus*, *Staphylococcus albus*, *Streptococcus pyogenes* and *Bac-*

terium coli. The entire clinical picture did not differ in these cases from that in the aseptic forms of nephritis. Neither was there any difference in the chemical constituents of the urine or of the appearance of the kidney when it was exposed. The results of operation in these cases were very much more satisfactory, however, than in aseptic cases, and Rovsing believes that his cases show definitely that unilateral chronic nephritis may be of infectious origin; that it may affect a greater or smaller part of the kidney, or that we may have a double partial infectious nephritis. Stripping off the kidney capsule, which gives such favorable results in cases of aseptic interstitial nephritis with perinephritis and severe pain, also has a favorable influence on inflammatory processes. In hemorrhagic cases he believes that splitting the kidney will give favorable results in the milder infections, such as by the *Bacterium coli*, but it is dangerous in the more virulent infections. Resection of the diseased part in case of local infectious nephritis which entirely resembled chronic aseptic nephritis led to cure in two of his cases.

Further investigation is needed to prove the value of Rovsing's suggestions. Up to this time infection with ordinary pyogenic bacteria has not been considered such an important etiologic factor in cases of chronic nephritis, though it might have been suspected that the cases following scarlet fever, erysipelas and other forms of infectious disease were of this character. The careful study of this class of cases which Rovsing suggests, if carried out by competent observers, could not fail to give important results. If further study of such cases proves that we can find such definite indications for operation as are above suggested a great advance has been made and undoubtedly many lives will be saved. The skepticism of many surgeons as to the advisability of operating in every case of this kind seems warranted from our present knowledge, and until definite grounds have been shown from more careful study of large series of cases by competent men, routine operation for chronic nephritis in any case can not be considered an established surgical procedure.

CLINICAL PARATYPHOID FEVER.

It seems clear now that there must be accepted a group of affections very similar to typhoid fever clinically, yet due to an essentially different etiologic factor. The cases of so-called typhoid fever affecting about 5 per cent. of all the patients presumed to be suffering from that disease in which no Widal reaction can be obtained, either during the course of the fever or the convalescence, are, in the light of recent investigations, due, not to the Gaffky-Ebert bacillus, but to a micro-organism of the colon bacillus family, having many morphologic and cultural similarities to the genuine *Bacillus typhosus*. The work done in elaborating distinctions between these closely allied bacillary groups which has occupied so many minds for so many years is now to have its reward, for certain at least of the colon

family are to be recognized as playing a distinct specific pathologic rôle in the enteric fevers of human beings.

It is not surprising that there should be an addition to the number of specific infectious fevers. Their number has grown constantly with the increase of diagnostic acumen and methodic observation. A century ago measles was not entirely differentiated from smallpox and diphtheria was as yet utterly confounded with scarlet fever. In recent years another specific infectious fever, German measles, has been added to the scarlet-fever-measles group of diseases, and a fourth affection, the so-called fourth disease of Dukes, is vindicating for itself a place beside the other three. It would be surprising, indeed, if further specific infections were not differentiated, for considering the large number of bacterial species known and recognized, only a very few (less than twenty) have been found to be pathogenic for man.

The point of main interest for the general practitioner is the possibility of the clinical recognition of these newly-separated affections. Paratyphoid fever is not a unit, but probably a disease group containing several members. The differentiation from each other and from true typhoid fever is the problem of the present decade. That this will not be easy without the refinements of bacteriologic diagnosis is clear. Paratyphoid fever may run a course so deceitfully like typhoid as to make clinical differentiation apparently hopeless. In a case cited by Dr. Longcope,¹ there was the febrile course of typhoid, rose spots, an enlarged spleen and the diazo-reaction, and two relapses followed the primary attack, while during convalescence from the second symptoms of thrombosis in the left leg developed. It is evident that only the absence of the Widal reaction and the discovery which was actually made in this patient of a paracolon bacillus in the urine, feces and rose spots could furnish proper basis for the differentiation of such a case from true typhoid fever.

While some cases are thus so completely similar as to make assured differentiation by clinical methods impossible, typical cases of paratyphoid fever usually present distinctive features that will at least arouse suspicion of their true nature. Dr. Nathan Brill,² in his paper before the New York State Medical Association at its last annual meeting, compiled a list of certain differences between these affections that have been noted by many observers. The incubation period of a paratyphoid fever is apt to be shorter than in true typhoid. The week's malaise is replaced by three or four days of discomfort, and then, instead of the gradual steplike rise of temperature, there is usually a rather sudden development of fever up to 104, or even higher. The sensorium is prone to be duller than in true typhoid and this apathy comes on earlier in the illness. This will call for a retention of some hint at least of the old name for the new affections, since it is the apathy of enteric fever that is expressed by the Greek root from which the name typhoid is derived. The look of pain in the face is

usually greater than in true typhoid and headache is more complained of. Constipation rather than diarrhea is a prominent feature. Paratyphoid fevers are, as a rule, shorter in their course, and after ten or twelve days there is a rapid lysis followed by more satisfactory convalescence.

These differential points constitute the clinical basis on which suspicions of paratyphoid fever must be aroused, especially in isolated cases under circumstances where the Widal and other serum reactions can not readily be obtained. It is not improbable that careful observation may disclose other diagnostic characteristics which will eventually make the clinical recognition of the new affections possible. In the meantime, a most interesting field for investigation lies open for the general practitioner.

PERIPHERAL NEURITIS AS A COMPLICATION OF GONORRHEA.

That infection with the gonococcus may extend by continuity of structure from the site of original inoculation has long been known, but it is only within comparatively recent times that the occurrence of dissemination through the blood stream has been recognized. The articular or synovial complication formerly designated gonorrheal rheumatism must be considered as having this latter origin, although it has not been established whether it is due to the invasion of gonococci or to the action of toxins elaborated by these. The endocarditis that has been observed and carefully studied in a number of instances has been shown to harbor the micro-organism itself.

A number of disturbances referable to the nervous system have also been described in connection with gonorrhea, and various explanations for their occurrence have been offered. Thus, paraplegia with wasting of the affected muscles in association with gonorrhea has been attributed to reflex influences, to myelitis secondary to ascending neuritis, to an impression on the trophic centers in the spinal cord and to specific gonorrheal infection. Myelitis and cerebrospinal meningitis have been reported in the same connection, and gonococci have been found in cases of the latter in the fluid obtained on lumbar puncture. Cerebral embolism, with hemiplegia and aphasia, may occur as a complication of gonorrheal endocarditis or phlebitis. With a knowledge of the fact that the activity of the gonococcus results in the production of toxic substances it can be readily understood that any portion of the nervous system may suffer in consequence of the effects of the latter.

In this way there may be produced a variety of disturbances attended with changes at the one extreme so slight as to be beyond detection with our present means of examination, and at the other extreme of the most marked character. If the lower segment of the motor tract is affected there will be developed the symptoms of poliomyelitis or polyneuritis, accordingly as the ganglion cells in the anterior horns of the spinal cord or the

1. Am. Jour. of the Med. Sciences, August, 1902, p. 209.

2. JOURNAL A. M. A., Nov. 8, p. 1205.

peripheral portion of the motor neuron is involved; both may even suffer together. Two extremely interesting cases belonging in this general category have recently been placed on record by Dr. T. R. Glynn.¹ The one occurred in a man, 48 years old, who presented, in conjunction with a urethral discharge in which gonococci were found, weakness of the lower, and later also of the upper extremities and of facial and ocular muscles, with abolition of reflexes, muscular wasting, degenerative reactions in some muscles, paresthesia, impairment of sensibility, involuntary discharges from the bladder and the bowel, delirium, delusions, acceleration of pulse and respiration and bed sores. Improvement set in in the course of a month and was slow, but it progressed to complete recovery. It is believed that in this case the entire motor neuron, but especially its peripheral portion, was injuriously affected by the toxin of the gonococcus, or possibly by that of an associated pyogenic coccus. The second case occurred in a young man, 17 years old, with gonorrhea of two months' standing, in whom there developed pain, tingling and weakness in the lower extremities, with abolition of knee-jerks and plantar reflexes, and from all of which recovery ensued.

If these cases be accepted as authentic instances of the complication of which they are reported as illustrative—and there is no sound reason why they should not—they add one more to the already numerous list of infections at times responsible for the development of polyneuritis.

THE CONSUMPTIVE'S CRIME.

According to a modern school of thinkers crime is practically a disease and the criminal should not be punished but should be cured. As a converse to this we have a large portion of the general public practically making disease a crime and cutting off the possibilities of cure while applying the punishment. Not long since a consumptive made nearly the round of the numerous hospitals of Chicago—according to the newspapers—and found himself barred from all. The only resource was to go as a pauper to an attachment of an almshouse in the suburbs.

This is not a unique experience; it has occurred in other cities, and the situation seems to be becoming aggravated. The medical profession has its responsibility for the state of affairs; it has for years been teaching the contagiousness of tuberculosis; health officials have promulgated the idea and just now the public are taking it up and acting accordingly. The unfortunate sufferer from pulmonary disease is beginning to find himself an outcast, a *persona non grata* even among those with whom he formerly associated; he is forbidden the health resorts where he once found benefit, and in many other ways is made to appreciate the fact that what was formerly only a misfortune has now become what, in its results as regards its estimation by the public, is practically a crime. This is not too strong a statement; it is amply warranted by actual facts. A well-

known pulmonary specialist tells that while he was camping in Colorado not long since he had to reply to an individual who was objecting to the vicinity of a consumptive by asking him whether he wanted the man taken out and shot, that being the natural available alternative in the case. It is only a few months since there appeared in one of the leading medical weeklies¹ an article by a physician not only insisting on the danger of contagion, but also charging consumptives as a class with a deliberate criminal tendency to spread their disorder.

THE JOURNAL has always maintained that the abject fear of tuberculous contagion was needless, and with reasonable and perfectly practicable precautions there is no danger in even the intimate association with consumptives. The experience of well-managed consumptive hospitals and sanatoria gives ample proof of this. Moreover, even without these precautions, but with otherwise good sanitary conditions, the danger is by no means as excessive as is commonly stated and supposed by the average layman whose fears have been aroused. In Great Britain, and in this country so far as statistics are available, the mortality from tuberculosis had steadily diminished with the improvement of the standard of living and better sanitation long before the general recognition of the germ and the present agitation for special prophylaxis of the disease.

The prospect of the complete eradication of tuberculosis, so much talked of just now, seems to us an *ignis fatuus*, perhaps of use as an ideal that will be always ahead of us, but not justifying measures that seriously diminish the aggregate of human comfort and happiness. There is no doubt, on the other hand, that by proper methods of increasing the individual resistance, not neglecting rational antisepsis against the germ, we can greatly diminish the mortality and make consumption, not the chief, but only one of the many unavoidable causes of the death which is the inevitable fate of us all. When it does come in this way let us make it easier to the victim, and not be adding to his misery by our selfish and irrational fear. We can also teach the public that the tuberculosis germ has by no means the fatal significance that they are learning to attach to it, that, while probably few if any of us escape it altogether, serious consequences result to only a small proportion of the whole. It is, when we consider the results, criminal to send out the misstatement that one-fifth, or even one-seventh, of the mortality is due to this disease. Probably in future years, and it may be in the near future, tuberculosis will be accounted only of secondary importance as a cause of death; it may even be, like other former scourges of the race at the present day, only a comparatively rare and negligible ailment, but if this is to be it will be through rational and humane methods and not reckless exaggeration and stimulation of insane public fears with their natural result of brutal inhumanity to the unfortunate.

EDUCATIONAL TOURS FOR MEDICAL MEN.

For several years tours to the various watering places and springs of France have been organized by the physicians of that country, thus allowing the participants to combine pleasure and instruction. Last summer two similar tours were planned in Germany, one embracing the saline springs of middle Germany, and the other the watering places on the North Sea. The latter tour began at Hamburg, and the tourists returned after spending eleven days at several of the most prominent resorts. They were carried on one of the steamers of the North Sea Line, which had been placed at their disposal. The men who planned and directed this tour have edited a book of 178 pages containing articles on the various resorts visited and on the influence of a marine climate. Many of the names occurring in the book are well-known writers and teachers.

Similar tours in Germany are to be made annually, and German physicians seem ready to follow the example of the French in this custom. In connection with the meetings of the medical societies in America and England trips have been planned to points of interest adjacent to the places of meeting, but these side trips have usually been for pleasure alone, any educational value attaching to them being secondary or accidental. In a few instances excursions have been planned by means of which parties of physicians have been enabled to visit and become familiar with the advantages of certain health resorts, but this has not been undertaken in any such a systematic way as is being done in continental Europe.

Very frequently medical men advise patients to go away from home for the benefit of their health, but usually the physician has little personal knowledge of the places to which the patients go, and he is often unable to give any but the most general directions as to what they should do when they reach their destination. Patients are sent to springs of various kinds because the waters are said to be good for certain diseases, but very often the physician is unacquainted with the composition of the water in question and with the way in which it is supposed to exert its influence. At such places one may see persons drinking powerful wafers, little knowing the effects which should follow their use, and with no medical direction. Many patients have been sent to places in the far west in the hope of favoring recovery from tuberculosis, only to become homesick and to return home disheartened after putting up with discomforts and privations which might have been wholly avoided if the patients had been sent to more appropriate places in the same region.

Carefully-planned and systematized tours for medical men could be arranged so that the springs, watering places, health resorts, etc., in a certain section of the country could be visited and pleasure be combined with the opportunity of gaining much useful information. The people who are financially interested in such re-

sorts and the transportation companies could well afford to bear the ordinary expense of such tours. As a result more patients would be sent to deserving places, and because of the increased knowledge of physicians as to the facilities and advantages of different springs, etc., patients would be sent to the places best suited to their particular cases and the results would be correspondingly gratifying. The planning and execution of such educational excursions would properly belong to the medical society, and the details would have to be worked out in each particular case. There seems to be no doubt that such trips might be of great value to all concerned, and just as profitable in this country as they seem to be in Europe.

A WISE JUDGE?

A Supreme Court judge in North Carolina¹ has decided that the practice of medicine and surgery in all its branches, as implied in the North Carolina medical practice law, consists solely in giving or prescribing drugs and performing surgical operations and that an osteopath and magnetic healer can not be considered as a medical practitioner under the law. It "can not be conceived," says this legal light, that the legislature would require one who eschews the use of drugs and surgery to pass an examination in anatomy, physiology, pathology, etc., which would be "useless knowledge to exact of an osteopath." This is in effect an intimation that any future legislation defining the practice of medicine, so as to bring osteopaths, magnetic healers, etc., under the law is impossible in the opinion of the Supreme Court; a sort of anticipatory judicial decision crippling the power of the legislative branch of the government, as a correspondent of the *Raleigh Post* points out. This is only possible by making it out unconstitutional, and what there is to justify it in the constitution of the state of North Carolina is beyond our knowledge. We shall watch with interest the future course of events in that state to observe how this judge-made fundamental law is taken by the law makers. The dictionary definitions that medicine is the science of healing and treatment of disease generally are ignored as well as their judicial recognition in other commonwealths. The English language, according to its standard interpreters, therefore comes under the condemnation of this spokesman of the Supreme Court of North Carolina. The medical profession in that state is, we believe, influential and numerous enough to bring about, if it tries, some legislation analogous to that in other states, defining the practice of medicine more in accordance with common sense and good usage than as laid down by this judicial authority, and it is to be hoped that the court as a whole may then give out a more creditable opinion.

MILLIONS FOR MEDICAL SCHOOL.

The extravagant statements with which the daily papers have been filled for the last few days regarding the new relationship between Rush Medical College and the University of Chicago, in which the writers play at battledoor and shuttlecock with millions, are, like the average so-called historical novel, founded on fact, and

1. See Medicolegal Department, p. 1278.

also like the historical novel, on very little fact. On account of possible misconception we mention briefly the progress and present status of the negotiations. For a considerable time Rush Medical College has been affiliated with the University of Chicago, and beginning with this year the first and second years' studies of the medical course have been taken at the university. The trustees of Rush Medical College, forecasting the increase in importance of the school, and appreciating the necessity of a permanent and sufficient endowment, without which their plans of increasing the length of the course of study and raising the standard could not successfully be carried out, early in the spring made a proposition to the university of organic union instead of affiliation, pledging themselves to raise the sum of one million dollars in case their proposition was accepted. The university considered the matter, approved it, and a few weeks ago presented it to the friends of the university in New York, who also signified their approval. It now remains only for the necessary legal steps as regard charter and so on to be taken by the trustees and for the promised million dollars to be obtained. It is not proposed that the name of Rush Medical College be lost, but that it be incorporated in the official designation of the university in some such way as "Rush Medical School of the University of Chicago." Of course, no one can say that eight million or eighty million dollars may not "ultimately be spent by the University of Chicago for building up Rush Medical College," but the facts just stated include all with which the authorities of the university and college are at present acquainted.

THE CORRESPONDENCE DIPLOMA MILL.

With the exit from business of the regular diploma mill of the Armstrong type, it must not be expected that the field is left unoccupied. As long as there is dupable material there will be found operators to work it up. One would think that the world would tire of being fooled, but until the weary cease from troubling them for their services the wicked will never be at rest. Among the circulars before us from concerns at present energetically seeking business we have one from Chicago which claims to be regularly chartered for the purpose of teaching the diseases of the eye, ear, nose and throat. It gives out its diplomas at the club rates of \$10 each, payable in five payments, semi-monthly, and the full and illustrated correspondence course of ophthalmic hypnotism thrown in for \$2.50 more. Residence or personal attendance is not necessary, as the instruction is given also by correspondence, and the circular naively says there is nothing about either diploma to indicate whether it was obtained by "correspondence" or a local course. It also furnishes "instructions how to advertise." Another institution reporting from South Bend, Ind., gives the degree of doctor of optics after a twenty-lesson correspondence course, at the club rates of \$7.50 to classes of 1,000. This looks as if its clientele had grown, as in its earlier circulars the same rates were offered to classes of 150, and the flooding of the country with \$7.50 "Doctors of Optics" is something rather serious to contemplate. It is of interest to note here in this connection that one of these concerns, the

Chicago one, claims that its correspondence course has been "openly endorsed by a number of medical journals," including among them the *Therapeutic Gazette*, *Medical Age* and *Medicine*. This, we think, must be a misrepresentation, as it is certain that our respected contemporaries would never have endorsed what is so evidently unethical as it appears to be from its circulars. It is possible that the merest mention is quoted as an endorsement; this is, indeed, suggested by an enclosed slip, attempting to make some general remarks by President Harper of the University of Chicago appear an endorsement of the course. Therefore, it is perhaps advisable for us to specifically and positively say that this notice is not an endorsement. If the medical authorities, the state boards of health and of medical examiners can not take up the matter, it might be one for the scrutiny of the postal authorities. These concerns certainly appear to be endeavoring to take in the public's money by advertising to give out wholesale a lot of diplomas and high-sounding titles with what must be pretty nearly a minimum of qualification.

THE SELF-ADVERTISING PRACTITIONER.

In a previous issue¹ we printed a clipping from a country newspaper which described the new equipment of a certain physician in such accurate terms that we expressed the opinion that the physician had assisted the editor in its construction. A number of correspondents have called our attention to what we are sorry to say is a too evident fact that some—not many we are happy to say—of the medical and surgical leaders of the great medical centers are not averse to similar newspaper notice. Some of our critics enclose newspaper clippings in support of their allegations. As an example, one correspondent calls attention to a two-column notice of the "Latest Triumph of American Surgery" in one of the best-known weekly lay publications of the day, where it appears with the portrait of a triumphant surgeon inserted between a champagne advertisement and others of Nabisco sugar wafers, Bee-man's chewing gum and Williams' shaving sticks. We have ourselves observed these things, and it pains us to think of the mortification such publications must give the eminent parties whose names are thus taken in vain. We remember a distinguished professor's lamentations over the sins of the reporters who, in spite of his expressed wishes, kept reproducing what purported to be verbatim interviews with him in regard to the notable features of his work that had an interest for the reading public. We are well aware that the newspaper man is ubiquitous, that his moral sensibilities are seldom fine enough to permit him to forego a scoop, and that any one who amounts to anything is liable to suffer at his hands. Those who are more distinguished will, of course, suffer more, but there are some who seem to suffer most, to have an idiosyncrasy, as it were, a special susceptibility to his attacks. There are some particularly shining marks who specially deserve the sympathy and condolence of the profession. Some men are born to be notorious, some achieve notoriety and some have it thrust upon them. No one can properly envy any one who has the misfortune of receiving the un-

1. THE JOURNAL, Oct. 11, 1902, p. 924.

ethical notoriety derived from what is, of course, undeserved and unauthorized newspaper puffery. For "Brutus is an honorable man; so are they all, all honorable men." But seriously, the contention of our correspondents is just. Criticism should be applied with equal force to him who stands high in the profession as to the unknown man of few friends and few attainments. There can be no two rules of conduct. If it is wrong for one physician to allow himself to be written up in the newspapers, it is wrong for another. The great city surgeon or physician whose conduct is dishonorable is a sad example to the country practitioner. The "leading lights" are supposed to lead in ethics as well as in diagnosis. If they do not, they are not leaders in a worthy sense. The fall of the tempted practitioner is often swift: surreptitious advertising, open display, exaggerated assertion, quackery. If he be encouraged in his course by his superior in skill, let the blame rest where it should. There is but one rule for both.

Medical News.

ALABAMA.

Alabama Medical College, Mobile, formally opened for the session of 1902-1903 with an address by the dean, Dr. George A. Ketchum, October 10.

Personal.—Dr. James M. Tubb, Bessemer, has been appointed company physician at the coal mines at Virginia.—Dr. Eugene D. Bondurant, Mobile, has been appointed a trustee of the Alabama Insane Asylum.—Dr. William M. Jordan, Birmingham, has become associated with Drs. J. D. S. Davis and W. E. B. Davis.

Birmingham Medical College Opens.—The ninth annual session of this college was opened, October 1, in the new college building, which has just been completed at a cost of \$30,000. Dr. Benjamin L. Wyman, dean of the college, delivered the opening address, and addresses were also made by President A. P. Montague of Howard College, and Drs. W. E. B. Davis and R. M. Cunningham.

COLORADO.

Maternity Re-opened.—The Denver Maternity and Woman's Hospital was re-opened, November 1, with a new corps of nurses, an incubator and a training school for nurses.

September Mortality.—During the month 819 deaths and 34 still-births were reported. The annual death rate was 17.02 per 1000. Typhoid fever caused 67 deaths, scarlet fever 7, and diphtheria 11.

Personal.—Dr. Frederick H. Welles, Victor, sustained a serious crushing injury of the right foot recently, in an elevator accident.—Colorado Sanitarium, Boulder, has secured the services of Dr. Howard F. Rand, Battle Creek, Mich., as medical superintendent.

Smallpox Quarantine.—At the semi-annual meeting of the State Board of Health an order was issued providing that the minimum period of quarantine for those suffering from smallpox shall be not less than four weeks from the beginning of the eruption, and in any case not less than ten days after sealing is completed.

Sanatorium to Remove.—The Rocky Mountain Industrial Sanatorium has given up its home near Barnum and will move to more commodious quarters near Denver. It is expected that the new sanatorium will be in running order by next spring. Tent life is one of the features of this home, and the Barnum location had not the space required for the tents and ground for cultivation. There have been 101 patients in the home, and probably this number will be greatly increased when the new home is finished.

DISTRICT OF COLUMBIA.

Many New Members.—At the October 1 meeting of the Medical Society of the District of Columbia, 55 new members were admitted.

Medical School Opens.—The medical school of Columbian University was opened October 1. Dr. Albert F. A. King,

dean emeritus, in his address reviewed the history of the school from the time of its organization in 1821 to the present time.

Post-Graduate School Incorporated.—Articles of incorporation for the Washington Post-Graduate Medical School were placed on record, November 1. The incorporators are: Drs. George M. Sternberg, Walter Wyman, Pressly M. Rixey, Robert M. O'Reilly, Alonzo B. Richardson, Samuel S. Adams, Edward A. Balloch, Swan M. Burnett, E. A. de Schweinitz, Joseph Taber Johnson, H. L. E. Johnson, George M. Kober, Sterling Ruffin, J. Ford Thompson, and William C. Woodward. There will be 104 professorships established: Six of preventive medicine, two of medical zoology, one of protective inoculations and serum-therapy and biochemistry, two of sanitary chemistry, eight of bacteriology, seven of pathology, fourteen of internal medicine and therapeutics, one of surgical anatomy, fourteen of surgery, six of military medicine and surgery, two of orthopedic surgery, nine of gynecology, six of obstetrics, two of mental and nervous diseases and electro-therapeutics, three of tropical diseases, four of diseases of children, two of diseases of the stomach, eight of diseases of the eye, eight of diseases of the nose, throat and ear, four of special diseases, and four of diseases of the skin.

ILLINOIS.

Cook County and Chicago.

Smallpox in Cook County.—In and adjacent to Evanston, a suburb immediately adjoining Chicago, and with a population of less than 20,000 by the last national census, there are now more than 40 cases of smallpox.

Bazaar for Lying-In Hospital.—A bazaar was held in the Palmer House parlors this week to furnish funds for the enlargement of the Chicago Lying-In Hospital and Dispensary, and for the establishment of a branch in the northwest district of the city.

Chicago Personals.—Dr. Arthur M. Corwin has been elected to the chair of physical diagnosis in the medical department of the University of Illinois.—Dr. D. A. K. Steele has so far recovered from his recent accident that he has resumed his professional work.—Dr. Henry F. Lewis has returned from Europe.

Needed Improvements at Cook County Hospital.—The county board will, it is hoped, at its next meeting, appropriate \$75,000 for a contagious disease ward, \$25,000 for a tuberculosis ward and \$25,000 for an alcoholic ward at the county hospital. Every ward at the hospital is crowded and the suggested improvements are urgently required.

Chicago's smallpox record during the year is remarkable, but it has been made so only through the constant reiteration of the virtue of proper vaccination. During the first ten months there were 310 cases, not one of which had ever been properly vaccinated. Out of the total number 4 died, 295 were discharged, and 11 remained in the hospital at the close of last week.

Chicago Deaths.—The total deaths for the week—469—are 30 more than for the previous week and 72 more than for the corresponding week of last year. This is equivalent to an annual death rate per 1000 of 13.43, and indicates an increase in the mortality rate of nearly 7 per cent. over that of the week before, and of more than 14 per cent. over that of the first week of November, 1901. The principal increase is in the deaths of those over 60 years of age from pneumonia.

County Institutions Crowded.—At the Dunning Insane Asylum nearly 1000 patients are compelled to sleep on the floor because of lack of space, and at the Dunning Infirmary similar conditions exist. It is expected that the county board, at its next meeting, will authorize the expenditure of \$350,000, divided as follows: Special building for convalescents, \$200,000; building for tuberculous patients, \$50,000; four additional cottages for insane patients, \$100,000.

INDIANA.

Dr. James E. Hibberd, Richmond, celebrated his eighty-sixth birthday, November 4.

Central Medical College Building Opened.—The new building of the Central College of Physicians and Surgeons, Indianapolis, was formally opened, October 31. Dr. Frederick C. Heath made the address of welcome.

Hospital for Sick Insane Ready.—The hospital for the sick insane, in connection with the Central Indiana Hospital for the Insane, Indianapolis, which has been erected and

equipped at a cost of \$132,000, was opened, November 5, for the admission of patients.

Flower Mission Hospital Begun.—Ground was broken, October 28, for the new hospital for incurables, advocated by the Flower Mission, Indianapolis, and rendered possible by the gift of \$5000 by an anonymous donor on the condition that a similar amount be raised by the mission.

Tuberculosis, in September, caused 338 deaths. Of these 141 were males and 197 females; 31 died under 5 years; 5 between 5 and 10; 6 between 10 and 15; 40 between 15 and 20; 52 between 20 and 25; 36 between 25 and 30; 36 between 30 and 35; 17 between 35 and 40; 23 between 40 and 45; 22 between 45 and 50; 18 between 50 and 55; 12 between 55 and 60; 15 between 60 and 65, and 27 beyond that age.

Out-of-Door Treatment for Tuberculosis.—According to the secretary of the State Board of Health, at least 15 Indiana consumptives who began the open-air treatment during the summer, will continue to live and sleep out of doors this winter. A few of them are having open-air houses built. These outdoor houses are frame, and consist of but one room, and it is entirely open on one side. A short strip of canvas, used as an awning and not a covering for the open side, is arranged to keep out the snow and rain, but not the air. Some will spend the winter on open porches or in tents.

IOWA.

Cornerstone Laid.—The cornerstone of the new St. Thomas Hospital, Marshalltown, was laid by Archbishop Keane of Dubuque, October 22. The hospital, when completed, will have cost about \$30,000.

Forty Years in Practice.—Dr. Joseph C. Krejci, Sioux City, celebrated the fortieth anniversary of his entry into professional life, November 3, by a dinner, at which he was presented with a gold-headed cane.

Unrecorded Physicians Arraigned.—The October grand jury summoned before it many Dubuque physicians who had neglected to file certificates with the county recorder, as required by law, and as a result, it is believed that none of the city practitioners is now unregistered.

Ellsworth Hospital Opened.—The new Ellsworth Hospital, Iowa Falls, has been formally opened. At the opening ceremonies addresses were made by Mayor J. H. Funk, Iowa Falls, and Drs. Daniel W. Crouse, Waterloo; Joseph L. Powers, Reinbeck, and J. Clinton Powers, Hampton.

No Certificate for Crofford.—The State Board of Health, November 5, decided to refuse to suspend the order revoking the certificate of Dr. J. W. Crofford, Lamoni, who some months ago was sentenced to a term in the penitentiary for murder resulting from a criminal abortion. He appealed to the Supreme Court, and the appeal is pending. Following his conviction his certificate to practice medicine was suspended. Dr. Crofford was released on bail pending the decision of his case by the Supreme Court. He took the ground that the Board of Health should not have suspended his certificate until it was settled by the Supreme Court whether he was justly convicted by the trial court. The board, however, has concluded to maintain its position, and the order of revocation stands.

KANSAS.

Resolutions Regarding Dr. May's Death.—At a meeting of the faculty of the College of Physicians and Surgeons, Kansas City, and at a meeting of the trustees of the same institution resolutions were adopted eulogistic of the late Dr. James W. May.

Personal.—Dr. Charles E. Caswell, Santa Fe surgeon at Holliday, fell from a train at that place, October 28, and fractured his right shoulder.—Dr. George H. Hoxie, Lawrence, has been appointed associate professor of anatomy in the University of Kansas, vice S. W. Willison.—Dr. Charles Lowry, Topeka, has been elected secretary of the State Board of Health, vice Dr. William B. Swan, deceased.

Washburn-Kansas Merger.—It is now reported that the merger of Kansas Medical College and Washburn will soon be fully consummated. The only question about which there has been any discussion is the retention of its own identity by the medical college. The medical college authorities desired that the college should be known as "The Kansas Medical College, the Medical Department of Washburn College," and while there was originally some opposition to this on the part of the Washburn trustees, they have now given their assent to it.

MARYLAND.

Robbery.—The residence of Dr. Henry W. McComas, Oakland, Allegheny County, was robbed November 4.

A memorial window in honor of the late Dr. William W. Duvall, Bowie, has been erected in Holy Trinity Church, Prince George's County, by his friends.

Smallpox on Elliott's Island.—Dr. John S. Fulton, secretary of the State Board of Health, reports an outbreak of smallpox on Elliott's Island, two men and a woman having the disease, supposed to have been brought from Bridgeville, Del.

Baltimore.

Death and Disease.—There were 166 deaths in the week ended November 7, of which only five were from typhoid fever. Measles and diphtheria are the most prevalent infectious diseases.

Friedenwald Memorial.—Memorial services in honor of the late Dr. Aaron Friedenwald were held at the McCulloh Street Synagogue November 9. Addresses were made by Rev. Drs. Mendes of New York and Schnuberger of Baltimore, and Cyrus Adler of New York, while the medical career of the deceased was discussed by Dr. Solomon Solis-Cohen, Philadelphia.

Personal.—Dr. John C. Hemmeter has been elected president of the Book and Journal Club, and Dr. John Whitridge Williams president of the Johns Hopkins Hospital Medical Society.—Dr. H. Clinton McSherry is in Paris.—Dr. Herman Brulle has been appointed medical agent for the southern district to treat the indigent sick in place of the southern dispensary.

The Vaccination Law.—The health commissioner of Baltimore, Dr. Bosley, has issued 100,000 blanks with the following notice: "The law directs that children be vaccinated before they are one year old. Parents and guardians are held responsible for failure to comply with this law. The law also provides that every citizen shall be vaccinated at least once. You will please see that the law is complied with in your family immediately. The vaccine physician of this ward is to be found at — street, office hours —, where he may be seen, or a postal card sent to the Health Department requesting a physician to call will receive prompt attention." This notice will be served on every householder in the city. The action is the result of a recent case of smallpox of a very mild type in Cumberland, which was not recognized, and in consequence 12 or 13 cases resulted from it.

Establish Memorial Lectureship.—Dr. and Mrs. Christian A. Herter of New York City have given \$25,000 to Johns Hopkins University for the foundation of a memorial lectureship in the medical department "designed to promote a more intimate knowledge of the researches of foreign investigators in the realm of medical science." This end is to be secured by inviting each year some eminent worker in physiology or pathology to deliver one or more lectures at the university on some subject with which he is especially identified. The lecturer will receive an honorarium, the annual income of the endowment fund. The committee to select the lecturer will consist of Drs. William H. Welch, William Osler and John J. Abel, and it is intended to continue this committee so as to represent pathology, physiologic chemistry and clinical medicine. There is no bar to extending the proposed lectureship to leaders in medical research in America if deemed advisable. Dr. Herter was a graduate student at the university in 1887-88, pursuing a special course in Dr. Welch's laboratory. He holds a chair in University and Bellevue Medical College, New York, and is a well-known contributor to the literature.

MASSACHUSETTS.

Bequest to Boston Hospital.—For a building, to be known as the Lamont G. Burnham Ward, \$150,000 is left to the Boston City Hospital by a codicil of the will of Lamont G. Burnham, ex-president of the Chamber of Commerce, who died at Manchester recently.

Officers and Staff Re-elected.—At the annual meeting of the trustees of Framingham Hospital, October 16, the old board of officers, staff and committees were re-elected. The vacancy on the consulting staff caused by the death of Dr. Zabdriel B. Adams, was not filled.

Endowment Depends on Merger.—The Lowell General Hospital and the Corporation Hospital of that city are to be merged into one institution, an endowment fund of \$100,000 having been promised by an anonymous benefactor on condition that the merger be effected.

Damages Against Physician.—In a suit recently decided in the Superior Court, a woman who had brought suit to recover \$5000 damages suffered by reason of the alleged negligence of the defendant, a physician and surgeon, of Boston, whom she had employed professionally, \$2000 damages were allowed the plaintiff.

Dr. Zakrzewska Eulogized.—A unique function in Boston, October 29, was a meeting held in memory of Dr. Marie E. Zakrzewska, founder of the New England Hospital for Women and Children. It was in reality a celebration of the advances made by women in medicine, and particularly the growth of hospitals for women, conducted wholly by women, though the subject matter of the proceedings was largely eulogy of the first great New England woman physician.

Decrease in Death-Rate.—Dr. Samuel W. Abbott, secretary of the State Board of Health, comments on the decrease in the death-rate in the state and its causes. The average annual death-rate for the past 50 years was a little over 19 per 1000, never rising higher than 22.8 per 1000, in 1872, and never until 1901 has it fallen below 17 per 1000. There has been a substantial drop in the death-rate from 20.8 in 1892, to 16.8 in 1901. If no great epidemic occurs before Jan. 1, 1903, the indications are that the death-rate of 1902 will prove to be as low as, if not lower, than that of 1901. The causes which he considers operative are the improved method of treatment whereby the death-rate from tuberculosis, typhoid fever, scarlet fever, whooping cough, puerperal fever and diphtheria has been decreased; the better organization of local health boards, with sanitary inspection and laboratory work, and finally to the change in the age-constitution ratio.

MICHIGAN.

To Combat Smallpox.—The Detroit Common Council in special session, October 31, instructed the city controller to audit bills of the Health Department to the extent of \$20,000 to meet the bills for the purpose of general vaccination and other expenses necessary to the prevention of the spread of smallpox.

The Most Dangerous Communicable Diseases.—Meningitis was reported present in Michigan during October, at 6 places; smallpox at 34 places; whooping cough at 35 places; measles at 42 places; diphtheria at 71 places; scarlet fever at 148 places; typhoid fever at 173 places, and consumption at 241 places. Meningitis was reported at 1 place less; smallpox at 5 places less; whooping cough at 3 places more; measles at 3 places less; diphtheria at 19 places more; scarlet fever at 45 places more; typhoid fever at 4 places more, and consumption at 10 places more, in October, than in the preceding month.

Personal.—Dr. and Mrs. Corydon M. Ryno, Benton Harbor, have returned from Europe.—Dr. William C. McCutcheon, Cassopolis, has been re-appointed physician of Cass County.—Dr. Willis Earle Chapman, after service in the Philippines, has returned to Sparta, via Europe.—Dr. Percy E. Wagar, formerly of Three Rivers, has been appointed secretary of the province of Benguet, Philippine Islands.—Dr. Johnston B. Kennedy, Detroit, left for Europe, October 28. He was tendered a banquet at the Russell House the previous evening. He expects to remain abroad until next spring.

Comparative Health of Michigan.—For October, compared with the preceding month, scarlet fever and diphtheria were more prevalent; and diarrhea, cholera morbus, inflammation of bowels, dysentery, remittent fever, cholera infantum, measles and smallpox were less prevalent. For October, compared with the average for October in the 10 years, 1892-1901, diphtheria, scarlet fever, whooping cough, measles and smallpox were more than usually prevalent; and diarrhea, typhoid fever, consumption, intermittent fever, cholera morbus, inflammation of bowels, dysentery, erysipelas, remittent fever, and cholera infantum were less than usually prevalent. The decreased prevalence of diarrhea and of the other diseases which prevail during the summer and fall months, may have been due to the unusually cold and wet weather of the preceding month.

Appeals to Supreme Court.—Dr. Peter Radabaugh, a graduate of the Miami Medical College, aggrieved at the refusal of the State Medical Board of Registration to grant him a certificate to practice medicine in Michigan, applied to the Supreme Court, November 3, to have an issue framed in which the facts in connection with the board's refusal could be determined. The court ordered a single issue settled. This was as to whether the board had arbitrarily refused to consider the question whether the college from which Radabaugh was gradu-

ated was a reputable college within the meaning of the law. The matter was referred to the Circuit Court for Ingham County for determination. The petitioner desires to have his certificate of graduation accepted as conclusive proof of his ability to practice medicine, and the state board claims that the college is not a reputable one within the meaning of the statute.

MISSISSIPPI.

Personal.—Dr. Hyman McM. Folkes, Biloxi, has been appointed a member of the State Board of Health, vice Dr. Benjamin D. Watkins, Natchez, resigned.—Dr. T. D. Bourdeaux, Meridian, has been appointed assistant physician at the East Mississippi Insane Hospital.

Status of Osteopathy.—The Supreme Court of Mississippi now has under advisement the question whether the osteopaths operating in the state are violating the laws regulating the practice of medicine. The question is brought up in the case of Hayden vs. State, appealed from the Circuit Court of Alcorn County, wherein the appellant was convicted of practicing medicine without license.

Improved Health of Mississippi.—The State Board of Health, at its annual meeting, reached the conclusion that the health situation of Mississippi was more satisfactory than it had been for several years. The reports of the county health officers show a notable absence of contagious and infectious diseases all over the state. A little smallpox remains in a few counties of the Delta, but this is gradually being suppressed, and in no section could it be regarded as epidemic.

NEW YORK.

New York City.

Propaganda Against Tuberculosis.—The Charity Organizations' tuberculosis committee has mapped out the following work of prevention, and even better results than those heretofore attained are hoped for: Investigation of the relation of the disease to overcrowding in infected tenements; publication by leaflets and lectures of the results of modern treatment; encouragement of the establishing of public and private sanatoria and relief of indigent consumptives by supplying proper food and lodging places.

Changes at Bellevue Hospital.—Dr. George T. Stewart, who has been superintendent of Bellevue Hospital, has been promoted to the new position of department superintendent, and his former deputy, Michael J. Rickard, who has been faithful to Bellevue for more than thirty years, has been appointed superintendent of that hospital. In his new position Dr. Stewart will have not only Bellevue, but Gouverneur, Fordham and Harlem hospitals under his supervision. An effort has been made by the trustees materially to raise the pay of orderlies and of various helpers in the hospital and to improve this part of the service. The inside of the old Bellevue Hospital Medical College building is now to be torn down and reconstructed as a modern dormitory.

Trance Ends in Death.—Mention has already been made of the young woman lying in a trance at St. Vincent's Hospital. After remaining in this state for thirteen days she was roused to consciousness for a short time, but lapsed again. However, she subsequently became conscious of her own accord, and told her mother that all she could recall was that she had gone to bed in her room and awakened to find herself in the hospital. After a trance lasting for twenty days the girl died in coma. The day before her death there was evidence of great exhaustion; the pulse rose from 136 to 156, and the temperature dropped to 100.8 F. The postmortem examination was made by Dr. Theodore C. Janeway, in the presence of a number of eminent physicians, after a number of tests had been applied to determine positively that death had actually taken place. A careful examination failed to find any gross lesion, and unless the microscopic study of the nervous system throws new light on the case its nature will continue to be in doubt.

PENNSYLVANIA.

Philadelphia.

Hughes Memorial.—Contributions are being made for the erection of a tablet at the Philadelphia Hospital in memory of Dr. Daniel E. Hughes.

Personal.—Dr. John H. Packard has returned from Europe.

Bequest.—By the will of the late Philip Jagode, a bequest of \$5000 for the founding of a free bed in memory of his wife was made to the German Hospital. Should his daughter die without children \$20,000 more will go to the same institution.

Typhoid Widespread.—For the week ended November 8 124 new cases of typhoid fever were reported. The disease is widespread throughout the city, there being only two wards free. The health authorities say that more than 500 cases of typhoid fever are now under treatment.

A Distinguished Visitor.—Dr. George C. Guillemin of Paris, chief of clinic to Dr. Raymond, Chareot's successor, recently spent several days in Philadelphia. He visited the Orthopedic, Philadelphia, Jefferson and University hospitals, and was entertained at dinner by Dr. Charles K. Mills.

The Keen-Wood Banquet.—At the banquet in honor of Drs. William W. Keen and Horatio C. Wood, November 6, Dr. John H. Musser was toastmaster. Dr. William Welch, Baltimore, proposed the toast "Medicine," to which Dr. Wood responded. Dr. William B. Coley, New York City, gave the toast "Surgery," to which Dr. Keen made response. Dr. J. Chalmers Da Costa spoke to the toast "The Pupil in Surgery," and presented Dr. Keen with a loving cup. Dr. Robert A. Hare replied to the toast "The Pupil in Medicine" and presented a loving cup to Dr. Wood. Among the 136 present were Drs. Abraham Jacobi and John D. Bryant, New York; Drs. Maurice Richardson, J. Collins Warren and Samuel J. Mixer, Boston; Dr. Allan McL. Tiffany, Baltimore, and Surgeon-General George M. Sternberg, U. S. Army (retired).

RHODE ISLAND.

Gift to Woonsocket Hospital.—Mrs. Chester B. Smith has donated the funds necessary to provide a new wing for the Woonsocket Hospital, which will include an operating room, emergency and anasthetizing rooms, etc.

Addition to Newport Hospital.—It is announced that Mrs. Cornelius Vanderbilt will provide an addition to the Newport Hospital, in memory of her husband. The new wing will cost \$100,000, and will be three stories in height, and 125 by 40 to 50 feet.

Personal.—Dr. Vernon M. Griswold, who some years ago removed from Fredonia, N. Y., to Westerley, has returned to his former home and resumed his professional work in Fredonia. —Dr. Mary Secord Packard, Providence, has accepted the position of resident pathologist at the New England Hospital for Women and Children, Boston.

GENERAL.

Many Post-Office Physicians Released.—By an order from the Postmaster-General, November 7, the position of post-office physician in all cities of less than 500,000 inhabitants is abolished as unnecessary. The saving to the government will amount to \$10,500 yearly. Ten physicians are released.

Trip to the International Medical Congress.—It is reported that many physicians will attend the International Medical Congress at Madrid, April 1903. Arrangements have been made for a party of physicians from the eastern states. The trip from New York and return will require about one month. Physicians and members of their families who join this party will be entitled to the special rate of \$265 for the round trip, including first-class passage on the steamer and railway, hotel accommodations for 14 days in Spain, including room, meals, all handling of baggage, special interpreter and fees. The trip will be via Gibraltar and Cordova to Madrid. There will be side trips to interesting parts of Spain at extra cost, and also returns by other routes for those who desire. Physicians in the eastern and middle states may secure more information from Dr. Ramon Guiteras, 75 West 55th Street, New York.

What Cities Lead in Disease.—The report of the U. S. Department of Labor gives health reports of many cities from which are taken the following summaries of the ten cities in which each disease named is most common:

Typhoid Fever.—Pittsburg, Minneapolis, Allegheny City, Kansas City, Louisville, Washington, Columbus (Ohio), Birmingham, Houston and Atlanta.

Malaria.—Houston, Memphis, Savannah, Charleston, Augusta (Ga.), Little Rock, Dallas, San Antonio, Wheeling and Montgomery. All it will be noted, in the South.

Scarlet Fever.—Knoxville, Salt Lake City, Denver, Boston, Pittsburg, New York, Reading (Pa.), Columbus (Ohio), Allegheny and Montgomery.

Diphtheria.—Minneapolis, Lowell (Mass.), Salt Lake City, Des Moines, Camden (N. J.), Hartford, Cleveland, Denver, Boston and Duluth (Minn.). New Orleans makes the best showing in this matter of any city in the Union.

Tuberculosis.—San Antonio, Schenectady (N. Y.), Rochester, Los Angeles, Mottla, Little Rock, Evansville, Troy, Washington and Houston. The presence of San Antonio and Los Angeles in this list will be understood as due to persons afflicted with tuberculosis prior thereto.

Pneumonia.—Birmingham, Troy, Worcester (Mass.), Saratoga (Pa.), New York City, Utica, Allegheny, Des Moines, Atlanta and Butte (Mont.).

Cancer.—Grand Rapids (Mich.), Portland (Ore.), Spokane, Rochester, Albany, Hartford, Cambridge, San Francisco, Oakland and Milwaukee.

Louisville may claim the title of the paralysis city, leading in that disease. Detroit in bronchitis, Rochester in heart disease, Cleveland in appendicitis, Albany is the center of Bright's disease for the country, but New York follows closely. Pittsburg kills most people by accidents, while San Francisco has a suicide record unequalled anywhere in the world and leaving Paris far behind.

The Naval Medical School was opened November 3. Medical Director R. A. Marmion, U. S. N., president of the faculty, made the introductory address to the class, giving the history of previous attempts to establish a school, the necessities therefor, and the scope of its projected work. Remarks were also made by Ex-Surgeon-Generals Gunnell and Van Ruyven and Dr. S. S. Adams, president of the Medical Society of the District of Columbia. The school is essentially post-graduate in its nature, and starts its instruction with the assumption that its students have received a thorough training in the general principles of the chief medical branches. The students are those already belonging to the Navy. The course will cover five months. The following is the faculty and the list of subjects to be treated by them:

Hygiene (of ship, camp and hospital) and Quarantine, Medical Director R. A. Marmion.

Duties of Medical Officers, Medical Inspector John C. Boyd.

Military Diseases and Tropical Medicine, Surgeon John W. Ross.

Military Surgery, Surgeon A. C. H. Russell. (In this course the Hospital Corps drill is included.)

Bacteriology and Chemistry, Surgeon E. R. Stein.

Ophthalmology, Passed Assistant-Surgeon T. D. Myers.

Instructions in Signals, Manual of the Sword and Extracts from Tactics, by an officer not yet designated.

Naval Law, Mr. E. P. Hanna, solicitor of the Navy Department.

The school occupies a portion of the buildings formerly used as the Naval Observatory, which have been remodeled in order to adapt them to the requirements of the new work just undertaken. The following assistant surgeons compose the class:

Beckmann, R. A., and Strize, H. F., Pennsylvania; Munson, F. M., Delaware; Brown, E. M., California; Hoyt, E. E., New Hampshire; Traynor, J. P., Maine; Baker, M. W., Virginia; McCoway, J. H., Kentucky; Neilson, J. L., Shaw, H., and Janness, B. F., Massachusetts; and Michaels, R. H., Illinois.

International Congress at Madrid.—The American Committee of the Fourteenth International Medical Congress announces that the following list of sections has been authorized:

1. Anatomy (Anthropology, Comparative Anatomy, Embryology, Descriptive Anatomy, Normal Histology and Teratology).
2. Physiology, Physics and Physiologic Chemistry.
3. General Pathology, Pathologic Anatomy and Bacteriology.
4. Therapeutics and Pharmacy.
5. Internal Pathology.
6. Nervous Diseases, Mental Diseases and Criminal Anthropology.

7. Pediatrics.
8. Dermatology and Syphilis.
9. General Surgery.
10. Ophthalmology.
11. Otolaryngology and Rhinology and Laryngology.
12. Odontology and Stomatology.
13. Obstetrics and Gynecology.
14. Military and Naval Medicine and Hygiene.
15. Hygiene, Epidemiology and Technical Sanitary Science.
16. Legal Medicine and Toxicology.

Subscriptions (25 francs, which is about \$4.75) must be paid before the opening of the congress to the general secretary, Faculty of Medicine, Madrid, and members should on paying the subscription state the section or sections to which they wish to belong. The Spanish committee of entertainment announces that the daily charge per person for lodging, service, light and three meals is, in hotels, from \$2.50 to \$7.00, and in private houses from \$1.75 to \$4.25. These sums include transportation from the station to the lodging and from the lodging to the station. As it is expected that Madrid will be crowded those who are to attend the congress are advised to apply for rooms as soon as possible to the Bureau des Logements, Faculté de Médecine, Madrid. Blank forms for these applications may be obtained on request from the secretary of the American committee. The Spanish committee on transportation makes no provision for trans-Atlantic travel. Their arrangements are made for receiving visitors at the port of entry and for transportation to Madrid. The French and Spanish railroads have granted delegates a general reduction of one-half on the fares. In the United States the Trans-Continental Passenger Association advises delegates to use the regular nine months' rate from Pacific points to Missouri River points. The American secretary is Dr. John H. Hoffmann, 125 W. 80th Street, New York.

CANADA.

Toronto Vital Statistics.—According to the returns issued by the City Clerk of Toronto, the number of births so far this year up to the 1st of November totals 4095, the number of marriages 1950, and the number of deaths 2685, as compared with 3579 births, 1762 marriages, and 2382 deaths for the corresponding ten months of last year.

To Report the Tuberculous.—The Board of Health of the city of Hamilton, Ontario, is considering a by-law to compel the reporting of all cases of tuberculosis to the medical health officer. Its passage has been recommended by the medical health officer, the Hamilton Medical Society and the mayor of the city.

Nova Scotia Sanitarium for Consumptives.—The provincial government of Nova Scotia is asking for tenders for the erection of a building for the purposes of a sanitarium for consumptives. The building, which is to be located at Kentville in King's County, will be two stories and occupy a frontage of 115 feet, and is to be built of wood. It will be fitted up with all the most approved modern improvements, and when completed will afford accommodation for some fifty patients. There will be a resident medical officer in charge.

Cataloging Canadian Scientific Literature.—Medical college authorities are coöperating in an undertaking by means of which it will be possible for scientific men to keep abreast of the scientific literature of the age. At the convention of scientific workers held at London in 1896, it was decided to establish an annual scientific catalog. Canadian publications will be cataloged by the following: Pharmacology, experimental pathology and bacteriology, Professor Adami of McGill University; human anatomy, Professor Primrose of Toronto University; physiology, Professor A. B. MacCallum of Toronto University, and botany, Professor Penhallow of McGill.

Keeping the Plague Out of Canada.—Dr. Montizambert, director-general of public health, Ottawa, states that Canada's immunity from the plague is due to the rigid system of quarantine observed. Not a single case so far has been reported at the William Head Quarantine Station on Vancouver Island. In addition to this the Canadian Pacific Railway authorities are very particular in inspecting Chinese passengers, boarding their vessels at Hong Kong and other ports. Referring to smallpox, which is epidemic in some parts of the western states, the director-general states it has been largely reduced, to such an extent that the staff of inspectors along the boundary line in British Columbia has been withdrawn for the present, except at a few points.

Scarlet Fever Serum Discovered.—Dr. G. A. Charlton, Rockefeller fellow of pathology at McGill University, is said to have just established some important results in the treatment of scarlet fever. Dr. Charlton gives the details of the serum which has been discovered by him in the current issue of the *Montreal Medical Journal*, and of 15 severe cases which he has treated, 13 made prompt recoveries almost free from complications. Of the 2 patients who died, 1 succumbed within five hours after admission, and the other was attacked with diphtheria, of which it died. The results noted in the treatment were a rapid subsidence of the fever, and absence and marked amelioration of suppuration in the middle-ear, and rapid convalescences.

Notre Dame Hospital, Montreal.—At the annual meeting of the board of governors of the Notre Dame Hospital, Montreal, held last week, it was stated that a new hospital with all the modern improvements, would be erected next spring at La-fontaine Park. Dr. E. P. Lachapelle, who was again elected superintendent, made the annual medical report. There have been treated within the last year 2132 cases, against 2200 for the previous year, the decrease being in every department except the gynecologic, where 33 more patients had been attended. The total number was divided into 1285 men and 847 women; the daily cost of each patient per day was 91 cents; 1813 were discharged as cured or improved; 185 were discharged with amelioration in their symptoms; 91 died in the wards, and 45 were brought in either dying or dead. This gives a mortality of 6.10 as against 6.09 for the previous year.

FOREIGN.

The cholera record in Egypt, from November 1 to 8, was 141 cases and 132 deaths.

Finland Women May Be Pharmacists.—By an official decree the profession of pharmacy has been thrown open to women in Finland.

Much smallpox in Barbadoes is reported. A week ago the total number of cases was 1200. The other islands are enforcing a strict quarantine against Barbadoes.

The Antimorphin Suit in Germany.—The *Deutsche Med. Woch.* published recently an article signed by Lewin containing an unfavorable criticism of antimorphin. The author and the editors of the journal were sued for damages by the proprietor. It has since transpired that antimorphin contains a considerable proportion of morphin and that the price is out of all proportion to the cost of the materials. The suit was dismissed.

To Prevent the Introduction of Ankylostomiasis.—The authorities at Trieste have issued a circular warning physicians and officials to be on the lookout for cases of ankylostomiasis in Italian workmen returning from Brazil. Instructions are appended in regard to the differentiation and prophylactic measures to be instituted. Compulsory notification of each case and strict isolation of the patient are required.

Professors Ribbert, Orth and Aschoff Transferred.—When Professor Orth of Göttingen was summoned to Berlin to take the chair left vacant by Gebhardt's death, Ribbert of Graz was invited to Göttingen in his place. Aschoff of Marburg is to take Ribbert's place. Aschoff has contributed a number of works to the literature on pathologic anatomy, and has also published recently a handbook for the easy study of the history of medicine.

Incomes of Medical Men in Paris.—The *British Medical Journal* says that there are said to be 2,600 medical practitioners in Paris; of these 40 have a gross income of \$40,000 to \$60,00; 50 of \$20,000; 50 from \$10,000 to \$20,000; 200 from \$6,000 to \$10,000; 200 from \$4,000 to \$6,000, and 1,700 earn on an average \$725, annually. In the whole of France, outside of Paris, there are 1,600 physicians whose individual gross income averages less than \$550.

The Continental Anglo-American Society.—This association of English-speaking physicians, residing in Europe and northern Africa, holds an annual meeting and banquet usually in October—this year at Paris. Next year they will meet at the same time and place as the British Medical Association. Dr. Bull of Paris is secretary, and Dr. Brandt of Nice, president. The objects of the society are mainly social and to serve as a professional link between the widely scattered members.

Trained Nurses in Germany.—The trained nurses of Germany are agitating a petition to the government to grant them an official examination after a three years' course of training, and a certificate for successfully passing the examination. This certificate can be withdrawn by the authorities in case of unworthy conduct on the part of the graduate. They also demand that the government should not appropriate funds for the support of hospitals which exact more than eleven hours of service from the nurses and which have not made adequate provision for pensions in case of old age and sickness. The government is also petitioned to supply means for an official three years' course of training.

The Campaign Against Charlatans in Germany.—The German laws do not condemn a charlatan unless he advertises what he knows to be false pretensions. Consequently the courts recently dismissed a suit against a quack as he seemed to be honestly convinced that his medicines or methods would accomplish all he claimed for them. The verdict stated that on account of the defective education and lack of previous special training, the accused was incapable of diagnosing cases correctly, and therefore had no intention to deceive when he asserted that he could cure them. The medical press comments on the utter perversion of justice in such cases, letting the quack go unscathed to further prey on the public, because of his ignorance, which should be the very reason for checking his career before he has done further harm.

The International Catalog of Scientific Literature.—This great undertaking commences with the literature of 1901. It is made possible by the co-operation of "regional bureaux" which collect all the scientific publications, pamphlets and articles in periodicals, published in their district and send the titles to the central office at London. The scope of the catalog embraces mathematics, mechanics, physics, chemistry, astronomy, meteorology, mineralogy, geology, geography, paleontology, general biology, botany, zoology, human anatomy, anthropology, physiology, pharmacology, experimental pathology, experimental psychology and bacteriology. A volume will be published annually in each of these branches of science, which it is seen embraces all of theoretical medicine. Each volume will be sold for \$5, and will contain the titles listed alphabetically by authors and subjects, in English, French, German, Ital-

dan or Latin. Purely scientific articles will be given the first place and then those on the borderland and technical articles that fall within the scope of the catalog. The financial support of the work is assured as the various governments interested have appropriated funds for the work of the local branches, and have also agreed to subscribe for a certain number of the completed volumes. Germany has appropriated nearly \$7,000 for the purpose for 1902. Twenty-eight countries have already made arrangements for the local co-operation. The number of periodicals to be reviewed is stated by the *Alg. Med. Ct.-Zg.* as 20 in Denmark, 55 in Holland, 31 in Japan, 28 in Norway, 19 in Portugal, 59 in Sweden, 6 in Southern Australia, 5 in Cape Colony, 41 in Canada, 197 in Italy, 435 in England, 853 in France, 1,255 in Germany and 1,500 in the United States. The entire work is the outcome and enlargement of the "Catalog of Scientific Papers" that has long been issued by the Royal Society of London. The total number of titles for the year now in press is estimated at 160,000. The volumes on botany and chemistry for 1901 have already appeared. Unless we are misinformed, the Smithsonian Institute has charge of the work in this country. The co-operation of Canada is mentioned in the Canada news of this issue.

LONDON LETTER.

Birth Palsy of the Sixth and Seventh Nerves.

At the Ophthalmological Society Mr. Nettleship described a case of this rare condition. Delivery was difficult in consequence of a brow presentation. The blades of the forceps were applied to the right mastoid region and in front of the left ear respectively. At birth the right eye was closed, and there were internal squint and spasms of the hands and arms. When three days old complete paralysis of the right face and internal squint were noticed. On the fifth day a small hemorrhage was detected in the right fundus below the disc. At the end of a month the paralysis had diminished, and after nine months it had disappeared. The injury was apparently a single intracranial hemorrhage at the base of the petrous bone involving the sixth and seventh nerves at that beginning where they are close together. Mr. Nettleship cited another case in which these two nerves suffered, but with separate lesions, the seventh by pressure of the forceps in the parotid region and the sixth by damage of the orbit. The eyelids in this case were swollen, and recovery was incomplete.

Ovarian Tumor Secondary to Breast Cancer.

At the Medical Society of London Mr. Bland Sutton described the case of a woman, aged 35, the mother of one child, whose right breast was removed in January, 1894. This was followed by recurrence three years and again four years afterward, for which excision was performed. In January, 1899, the left breast was involved and was removed. The patient remained well for two years, but in January, 1902, a tumor appeared in the abdomen, and was removed in March. Five gallons of fluid were removed in addition to a large solid ovarian tumor, exhibited. The tumor measured 7 inches in its two chief diameters, was dense, hard, and presented the typical microscopic structure of mammary cancer. The case was the most remarkable example of cancerous growth in the ovary secondary to cancer of the breast which has come under Mr. Bland Sutton's observation. The case raises the question of the frequency with which cancer attacks both breasts concurrently or after an interval of months or years. Both conditions are very unusual. Mr. Bland Sutton has come to the conclusion that when a woman has one breast removed for cancer she is five times more likely to have secondary deposits of cancer in one or both ovaries than in the remaining breast.

Correspondence.

The Immunization Treatment of Hay Fever.

NEW YORK, Nov. 1, 1902.

To the Editor:—At the last meeting of the American Laryngological Association, Dr. E. Fletcher Ingals of Chicago read a paper which you published in *THE JOURNAL* of June 28, 1902, concerning the immunization cure of hay fever. In this paper there are so many statements that are at variance with facts and so many misrepresentations in regard to myself, that I am obliged to ask you to publish this letter.

Ingals writes: "Dr. Curtis stated that by trying various substances he found that if a patient was rendered immune to one, he was thereby also made immune to some of the others. Curtis employed only the liquor ambrosia prepared by Fraser

& Co., the constituents of which are not given," and on page 1686, "Fraser's liquor ambrosia is a proprietary preparation, the constituents of which are not known to the profession; therefore, careful physicians will hesitate to recommend it, and when it is taken no one can know certainly to what its good or ill effects may be due."

In the same article he says: "As many patients are affected by the pollen from golden rod, it appeared to us best to use preparations from both this and ragweed, instead of relying on either one alone."

After describing the products of ragweed and golden rod he continues: "Before we discovered the preparations, the hay-fever season was so nearly on us that some of our patients were clamoring for relief. To one of these I gave Fraser's liquor ambrosia with careful instructions for its use, but he happened to be a man peculiarly susceptible to the influence of drugs, from some of which he had previously experienced, unpleasant symptoms. After taking a few doses of the liquid, his stomach was disturbed and he felt uncomfortable sensations, which appeared to him like those he had formerly experienced from taking an opiate; therefore, he declined to take it. As we were not familiar with the composition of this liquid, we could not urge its continuance, but within a few days we secured the preparations above referred to and decided to administer them together, but free from any other drugs, hoping thereby to obtain some accurate information for the benefit of hay-fever sufferers."

The entire tenor of his article makes it appear that he is doing a noble work with simple fluid extracts, and an insinuation is conveyed that I am using in my experiments a secret compound made by Fraser & Co. called liquor ambrosia.

My best answer to him is an extract from my article in the *New York Medical Record* of July 13, 1901: "The experiences narrated above prompted me last summer to obtain, through a drug firm, the services of a botanist to secure the flowers and pollen of enough ragweed to make an experiment on a large scale this year, on so-called hay fever, and to determine whether the hypothetical deductions from the experiments I have already conducted are truly as important as I believe them to be. The tincture and the fluid extract are the solutions most available. In my recent experiments I have discontinued the use of hypodermic medication. In the title of this paper the term hay fever is used in its popular sense, but the malady to which the treatment I have suggested applies is ragweed corasthma. I have several cases on record of golden rod and lily of the valley corasthma, which have been cured by *Solidago odora* and *Cavallaria majalis*, respectively, in three or four days; but, while these are interesting as contributive evidence, the old enemy, ragweed, is the recognized king of pollens, whose term of office begins August 12 to 20 in these latitudes and whose cruel reign is only ended by the first frost.

If my theory be correct, that this "rhinitis vasomotor periodica" or "corasthma ambrosia" may be prevented by giving from two to ten drops of the tincture or fluid extract of *Ambrosia artemisiifolia* t. i. d. in water, p. c., during the two weeks preceding the paroxysm, I shall consider that I have heralded what I believe to be an important discovery with becoming modesty. If, on the other hand, the results I have obtained are not verified by others, I may only say that greater men and more scientific observers have been misled by initial results that time did not substantiate. I should be pleased, however, to give to any physician who will conscientiously aid me in investigating the subject, such directions that he may experiment for himself on severe cases, in order that a collection of reports from disinterested physicians in widely separated localities may be of benefit to the cause of scientific research. In August, 1900, Fraser & Co., at my suggestion, combined the fluid extract of ragweed with aromatics in order to disguise its unpleasant taste and make it more palatable to the patient. With every bottle sent out, in reply to inquiries from the profession, a blank which read as follows, was enclosed," etc.

If, after reading my second year's report, published in the *New York Medical Record*, July 13, 1901, Dr. Ingals says that he does not know what the preparation liquor ambrosia con-

tains, and that it is a proprietary preparation unworthy of confidence, he states what is not true. I have told to every physician who has taken pains to inquire of me that the preparation made by Fraser is a fluid extract simply rendered more palatable by the addition of aromatics which are in the pharmacopeial sense drugs without chemical action and used as flavoring material.

In my investigation as to immunization of hay fever I have attempted to give every physician who has asked me for details the fullest directions and assistance, and have explained the manner of preparation of the tincture, the fluid extract and the liquor. What the particular aromatic flavoring extract was that Fraser used in the preparation of ambrosia, I never asked until I read the article of Dr. Ingals. I knew that the judgment of his chemist was better than my own as to what carminative aromatic would best disguise the unpleasant taste of the ragweed, and with every bottle dispensed was the explanation in Fraser's notes that it was the fluid extract of ragweed with aromatics.

As the medicine was used experimentally, I commenced with five drops to the teaspoonful, but later increased the dose to eight.

In my forthcoming report I shall tabulate the results in the treatment of some 8000 cases, and will in the future, as I have in the past, give to the profession every point it may wish to know. Had Dr. Ingals taken the trouble to write to me for the formula of liquor ambrosia, he would have received it.

In investigating the subject of immunization, in order to obtain exact results it was necessary to do two things: First, to have the flowers collected when the pollen was ripe, for I could not rely on the extracts I found on the market. Second, in order to know that cases treated were really treated with the fluid extract made from flowers in the proper stage of development, I was obliged to call my own preparation by a distinguishing name, simply for identification. Any preparation is proprietary when it bears the maker's name. Parke, Davis & Co.'s extract *Ambrosia artemisiaefolia* is proprietary—just as much as is Fraser's liquor ambrosia. In every chemical investigation we must first know the purity of our drugs. To this end I made every endeavor to make my experiment scientifically accurate. Until I announced my final results I did not care to have every druggist in the land put his own preparation on the market, and so I protected mine with a chemist's name. Certain safeguards have been found necessary by every careful investigator, to protect himself from exactly the style of medical plagiarism and captious criticism contained in the article above mentioned.

H. HOLBROOK CURTIS,

118 Madison Avenue.

CHICAGO, Nov. 5, 1902.

To the Editor:—I have carefully read and re-read Dr. Curtis' letter referring to my article in the issue of June 28, and I am unable to discover anything whatever to substantiate his statement that "In this paper there were so many statements that are at variance with facts and so many misrepresentations with regard to myself that I am obliged to ask you to publish this letter."

The Doctor seems to take special umbrage at my statement: "Fraser's liquor ambrosia is a proprietary preparation, the constituents of which are not known to the profession." He says further: "The entire tenor of this article makes it appear that he is doing a noble work with simple fluid extracts and an insinuation is made that I am using in my experiments a secret compound made by Fraser & Co., called liquor ambrosia."

In answer to the above, I submit a copy of the essential features of the label taken from a bottle of their preparation which I obtained this morning in an unbroken package from Fraser & Co.'s own drug store in this city. Beside this label the package contained nothing excepting a small blank reiterating the name, stating that cocain must not be employed as an adjunct, and suggesting that although the treatment had given great relief to a few cases on whom it had been tried, yet it was still in an experimental stage, and adding: "The physician who uses this bottle of medicine will confer a favor

by returning this blank, properly filled out, to Fraser & Co., who will acknowledge the same." Then follows a blank for the patient's name, age, and a few points concerning the attack and the patient's heredity, and whether or not he uses alcoholic beverages or smokes excessively, etc.

The label reads: "Liquor Ambrosia (Curtis) for the Prevention of Hay Fever." Following this is a statement that this preparation is used to immunize those affected by this disease, and that cocain must not be employed as an adjunct; also full directions for administration. (Observe the Doctor's noble purpose in furnishing his prescription gratuitously, at a dollar and a quarter a bottle for the medicine, to eight thousand suffering human beings.) Following this is the name and address of the firm. In fact the stuff is put up like patent medicines, in 8-oz. bottles, for sale directly to the public, and there is nothing whatever on the label excepting the ambiguous word "ambrosia" to give any clew to its contents.

Regarding my statement that it was a proprietary preparation, I quote from the latter part of the Doctor's letter: "I was obliged to call my own preparation by a distinguishing name simply for identification. Any preparation is proprietary when it bears the makers name. Parke, Davis & Co.'s extract *Ambrosia artemisiaefolia* is proprietary just as much as Fraser's liquor ambrosia." A proprietary preparation in medicine is correctly understood, and indeed is defined by Gould as "A medicine made by a private formula, sold under a copyrighted name, or the preparation of which is not free to the pharmaceutical profession." Parke, Davis & Co.'s extract *Ambrosia artemisiaefolia* is therefore not proprietary, as the formula is published outright on every bottle. The so-called liquor ambrosia (Curtis), on the other hand, is proprietary, as it is put up by Fraser & Co. and sold under a name that conveys no idea whatever of its real contents and without explanation of its formula despite Curtis' assertion to the contrary.

He states that with every bottle dispensed is an explanation that it is a fluid extract of ragweed with aromatics. In answer to this I may say that all who have had occasion to censor the advertisements offered to medical journals must have often observed this stock statement used by manufacturers who wish to conceal the composition of their preparations. No explanation that this was a fluid extract accompanied the package that I purchased to-day or any of the other bottles that I have seen.

He complains that I did not write him to learn its constituents. I did write him some months previously about the treatment, but did not receive a satisfactory answer. I did not write him, indeed I never write to any one to ascertain the composition of their proprietary preparations, for I am not interested in so-called medicines that are advertised without a formula of their constituents.

Inasmuch as my article gave full credit for whatever he had done, and did not contain a single sentence or phrase taken from any of his writings (excepting that taken from the pharmacopeias for which I gave them credit, and which possibly the Doctor forgot was not original with him), it appears that our amiable friend is hurling naughty names a little promiscuously in the last sentence of his letter.

34 Washington Street.

E. FLETCHER INGALS.

The Accuracy of European Retinoscopy.

CHICAGO, Nov. 1, 1902.

To the Editor:—In THE JOURNAL of Nov. 1, 1902, page 1107, Dr. Geo. M. Gould of Philadelphia uses the following language: "That there is probably not an 'ophthalmic surgeon' in all Europe who can use this method (retinoscopy) with accuracy shows how far we are as a profession from knowing our science, practicing our art, or doing our duty."

I admire Dr. Gould in all his scientific work and can follow his enthusiasm wherever it may lead, but I can not pass uncorrected such language from the editor of *American Medicine*, who has always advocated accuracy in language and diagnosis. To commit such an unpardonable sin of ignorance and unwarrantable discourtesy to foreign confrères, is to belittle his own argument. I have recently had the pleasure of a rather extens-

ive tour through some of the best of German university hospitals, and in nearly every clinic I saw retinoscopy practiced as a routine method, and instruction given to students by competent assistants in refraction with this method as a guide. Recent German periodic literature has numerous examples and illustrations of the method of teaching retinoscopy. At the Heidelberg Congress (August, 1902) Pflüger of Berne presented for approval the most elaborate apparatus I ever saw, and stated that it was only after use in his own clinic that he brought it to our notice.

In one private hospital—not belonging to a university and not used for teaching—the resident oculist spent over an hour a day in his dark room with the retinoscope estimating the refraction of the patients.

I have no doubt that the accuracy of these men would meet Dr. Gould's approval. Germans have long ceased to belittle the work of Americans, and we must avoid the error of supposing that what is done well here is therefore ignored or done ill there.

ALBERT B. HALE, M.D.

103 State Street.

COMMENT BY DR. GOULD.

PHILADELPHIA, Nov. 6, 1902.

To the Editor:—In reference to the courteous note of Dr. Hale I would say that in my opinion:

1. The best method of retinoscopy, when carried out by the most expert, is not trustworthy when subjective methods are possible with intelligent people.

2. No method of retinoscopy is accurate, not even the best one, except under cycloplegia. The Germans do not use cycloplegia.

3. The only use of retinoscopy advocated in my paper was for children. The Germans do not refract little children of from 2 to 6 years of age.

4. The great value of refraction is to diagnose and correct astigmatism. The Germans do not diagnose, correct or care for astigmatism, at least in those minor degrees, which produce the greatest eyestrain.

5. The method of retinoscopy used by the Germans is the old-fashioned one of Cuignet, which is utterly inaccurate and untrustworthy. The new method of Thorington, Jackson and other Philadelphia oculists is unknown, and their books untranslated in German.

6. It is not a question of "discourtesy" or "belittling." It is simply one of accuracy in statements. Mine were, and remain, absolutely true.

GEO. M. GOULD.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

REMEDIES FOR OBESITY.

RED CLOUD, NEB., Nov. 2, 1902.

To the Editor:—1. Is there a reliable remedy or treatment for obesity? 2. Is there any recent literature of any value on this subject?

R. F. R.

ANS.—1. No. Each case is a problem by itself. 2. Among the more important literature is the series of articles by Von Noorden in the *International Medical Magazine* during the past few months. Some of them are abstracted in *THE JOURNAL*. See *THE JOURNAL* of July 19 and September 20, pp. 168 and 725 respectively.

LIABILITY OF PHYSICIAN WHEN FREE SERVICE IS GIVEN.

CHICAGO, Nov. 6, 1902.

To the Editor:—Is a physician liable for injuries produced by electrotherapy (including x-ray) if services are rendered free—at a free dispensary? As I understand a lawyer is not responsible unless he collects.

W. C. E.

ANS.—A physician—or a lawyer—is as responsible for his acts when rendering his services gratuitously as when he receives remuneration for them.

PROCESS OF LAW AGAINST UNRECORDED PHYSICIAN.

NEW JERSEY, Nov. 10, 1902.

To the Editor:—There is a regular physician in this county who has been practicing for eight or nine years and has never been registered in the county clerk's office as required by law. Which is the proper way to go about it so as to have him comply with the law?

ANS.—Unless the state law of New Jersey exempts persons practicing before 1894 and the party in question comes under this provision, it would seem to be a case for the district attorney to investigate. The duty of lodging a complaint with him would seem to us to fall on the county medical society, though, of course, anyone might do so. Has the physician's attention been called to the oversight? Your county attorney can give you the exact law.

Book Notices.

TEXT-BOOK OF ANATOMY. Edited by D. J. Cunningham, F.R.S., M.D. (Edin. et Dubl.), D.Sc., LL.D. (Glasg. et St. And.), D.C.L. (Oxon.), Professor of Anatomy and Chirurgery, Trinity College, Dublin. Illustrated with 824 Wood Engravings from Original Drawings, Many Printed in Colors. Cloth. Pp. 1309. Price, \$1.75. New York: The Macmillan Co. 1902.

The medical student of to-day has a much broader range of choice in text-books than was the case a few years ago, and the text-books, moreover, are vast improvements on those that preceded them. This is true of all recent text-books on anatomy and of the present one in particular. While it may not be more generally convenient or better for the student than the later editions of Gray and Gerrish, it has the advantage of being in some respects a little more up to date. The editor speaks in his preface of the disadvantages of the composite work by different authors from the possibility of overlapping of subjects or differences of opinion, but we see nothing in the present work that would detract from its importance on these accounts. The different subjects are by authors of well-known reputation and are most ably handled. This work differs from others in its less conventional method of description and arrangement. Thus the topical relations of the viscera have been treated with reference to the most recent methods of hardening and preparation and the descriptions are decidedly the better for it. As for the special parts of the work we would speak of that on general embryology which in some respects is more complete and up to date in regard to the most recent discoveries than anything we have seen in the line of text-books of anatomy. The same may be said also of other parts. The illustrations are admirable, many of them schematic, and are the better for this reason. The use of color is introduced to a great advantage where it is employed. The book is one that can be honestly recommended.

THE PRACTICAL MEDICINE SERIES OF YEAR BOOKS, Comprising Ten Volumes of the Year's Progress in Medicine and Surgery, Issued Monthly. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Volume IX. Physiology, Pathology, Bacteriology, Anatomy. Pathology Edited by W. A. Evans, M.S., M.D., Professor of Pathology, College of Physicians and Surgeons, Chicago. Bacteriology Edited by Adolph Gehrmann, M.D., Professor of Bacteriology, College of Physicians and Surgeons, Chicago. August, 1902. Cloth. Pp. 212. Price, \$1.25. Chicago: The Year-Book Publishers.

This book consists of series of abstracts of articles that have appeared within a year or so of its issue, upon subjects connected with physiology, pathology, bacteriology, anatomy. We fail to understand why the names of W. T. Eckley and B. Fantus, authors of the sections on anatomy and physiology respectively, are not mentioned on the title page as well as those of the reviewers of pathology and bacteriology. The work seems well done as far as it goes. The careful reader will miss an author's index, which is especially desirable in works of this kind. In pathology the work of American investigators is given full share of the space. On the whole this volume compares favorably with its predecessors.

A TEXT-BOOK OF HISTOLOGY AND MICROSCOPIC ANATOMY OF THE HUMAN BODY, Including Microscopic Technic. By Dr. Ladislaus Szymonowicz, A.O., Professor of Histology and Embryology in the University of Lemberg. Translated and Edited by John Bruce MacCallum, M.D., Johns Hopkins University, Baltimore. Illustrated with 277 Engravings, Including 57 Plates in Colors and Monochrome. Cloth. Pp. 435. Price, \$4.75 net. Philadelphia and New York: Lea Brothers & Co. 1902.

This book in all probability will take its place among the first favorites of the text-books dealing with the subject of which it treats. There is no criticism to offer of the manner in which the subject is presented. Possibly the section on microscopic technic will be found rather short and not complete enough to replace satisfactorily special works on technic. The publishers have done their part well. The illustrations are all creditable, some being excellent. The translator and editor has given due attention to recent American investigations in histology and microscopic anatomy.

Marriages.

CHAUNCEY T. SCUDDER, M.D., to Miss Annie R. Auld, at Baltimore, October 29.

EDWARDS H. PORTER, M.D., to Miss Harriet Noble, both of Tiffin, Ohio, October 29.

ROLAND A. FELT, M.D., to Miss Florence G. Bullen, both of Perry, Okla., October 29.

CRAIG BARROW, M.D., Savannah, Ga., to Miss Alice Barker of Atlanta, Ga., October 30.

THEODORUS BAILEY, M.D., to Miss Alice Van B. Foos, both of New York City, November 1.

BENJAMIN HARBASON, M.D., to Miss Layla Kritz, both of Waveland, Ind., November 5.

WALTER LEE STRAUGHAN, M.D., to Miss Nelle Kritz, both of Waveland, Ind., November 5.

L. G. NOEL, M.D., to Miss Augusta Dickel Jonnard, both of Nashville, Tenn., October 30.

JAMES W. STONE, M.D., to Miss Virginia Lockett, both of Henderson, Ky., November 5.

J. EMMET LEAHY, M.D., to Miss Margaret Eugenie Slattery, both of Chicago, November 1.

CARL L. SPOHR, M.D., to Miss Hattie Wirthwein, both of Columbus, Ohio, November 4.

OSCAR L. HOLMES, M.D., Stewart, Ga., to Miss Cleo Aiken of Covington, Ga., October 22.

PHILIP FOX, M.D., Madison, Wis., to Miss Katherine Brigham of Milwaukee, October 29.

SAMUEL GORDON TODD, M.D., Neenah, Wis., to Miss Jennie Reyniers of Chicago, November 3.

ABRAM J. BARKER, M.D., to Miss Lucy Burr Wadhams, both of Torrington, Conn., October 28.

HOMER J. HALL, M.D., Franklin, Ind., to Miss Mary Hadley of Bloomingdale, Ind., November 6.

CHARLES M. JACOBS, M.D., Chicago, to Miss Helen Thalheimer of Richmond, Va., October 27.

Deaths.

Episcopal, Methodist, Children's and Pennsylvania hospitals, and gave especial attention to diseases of children. His contributions to the literature were numerous and valuable. Those especially noteworthy are those on diseases of the heart, typhoid fever, trichinosis, Paget's disease and visceral relations of tonsillitis. He was a member of the American Medical Association, the Association of American Physicians, American Pediatric Society, Philadelphia College of Physicians, Philadelphia County Medical Society, Philadelphia Neurological Society and president of the Philadelphia Pathological Society and the Philadelphia Pediatric Society. In 1901 he was elected a trustee of the University of Pennsylvania, and during the college year 1901-1902 lectured on therapeutics in the University of Pennsylvania, during the absence abroad of Dr. Horatio C. Wood. In addition to his exceptional professional talent which had already placed him among the foremost clinicians of the east, he possessed a singular charm of personality. In October he was attacked by typhoid fever, followed by appendicitis, for which an operation was performed. On October 31 perforation occurred, and the operation performed, therefore, was of no avail, as he died the next day from exhaustion.

Francis F. Davis, M.D. University of Michigan, Ann Arbor, 1867, a member of the American Medical Association, and one of the most eminent professional men of western Pennsylvania, died suddenly from organic heart disease, in Oil City, while making a professional call, October 31, aged 64. He was a native of western Pennsylvania; served during the Civil War as assistant surgeon of the One Hundred and Twenty-first Ohio Volunteer Infantry. At the close of the war he settled in Oil City. He was a member of the International Association of Railway Surgeons, Medical Society of the State of Pennsylvania, Venango Medical Society and Oil City Academy of Medicine.

Frank A. Holland, M.D. University of Minnesota, Minneapolis, 1886, for five years on the staff of hospitals in St. Paul and Minneapolis, then an assistant surgeon in the army for two years, and thereafter a practitioner of Dubuque, Iowa, died at his home in that city, October 29, from typhoid fever, after an illness of six weeks.

James Johnston Bell, M.D. Rush Medical College, Chicago, 1886, one of the founders of Kedzie Hospital, and one of the best-known practitioners of northwest Chicago, died at St. Luke's Hospital, November 4, after a long illness from gliosarcoma of the brain, for which he underwent an operation the day before his death, aged 41.

Robert C. Kedzie, M.D. University of Michigan, Ann Arbor, 1851, during the Civil War surgeon of the Twelfth Michigan Infantry, and for more than 40 years professor of chemistry at the Michigan Agricultural College, Lansing, died at his home in that city, November 7, aged 79.

W. Clark Allen, M.D. Northwestern University Medical School, Chicago, 1894, surgeon at the Kedzie Hospital, Chicago, died suddenly from hemorrhage of the lungs after alighting from a street car in front of the hospital, November 4, aged 37.

John James May Angear, M.D. Rush Medical College, Chicago, 1860, one of the founders and faculty of the College of Physicians and Surgeons, Chicago, died at his home in Chicago, November 8, from chronic endocarditis, aged 73.

Charles M. Bethauser, M.D. Starling Medical College, Columbus, Ohio, 1882, a well-known clergyman and physician of Columbus, died at his home in that city, October 30, from liver disease of long standing, aged 68.

Andrew J. Manville, M.D. Bellevue Hospital Medical College, New York, 1866, one of the oldest physicians of Bowling Green, Ohio, was instantly killed by being struck by an express train, at Custar, November 3, aged 68.

John H. Abbott, M.D. Jefferson Medical College, Philadelphia, 1872, an esteemed citizen and twice mayor of Fall River, Mass., died at his home in that city, November 1, from pneumonia, after a short illness, aged 54.

Gerard M. Muller, M.D. University of Utrecht, Holland, was found unconscious in his rooms at Grand Rapids, Mich., October 31, and was taken to Butterworth Hospital, where he died, November 3, aged 70.

Andrew J. Schmidt, M.D. McGill University, Montreal, 1886, died suddenly at his residence in Cedar Rapids, Iowa, from heart disease consequent on rheumatic arthritis, November 3, aged 39.

Robert L. Wood, M.D. Kansas City Medical College, 1873, son of the late Dr. Joseph Wood of Kansas City, died in that city, from fatty degeneration of the heart, October 31, aged 62.

John C. Drake, M.D. Western Reserve University, Cleveland, Ohio, 1868, died at his home in Oakley, Mich., November 1, aged 60.

New Instrument.

A WIRE LOOP FOR AURAL SNARES.

HAROLD WILSON, M.D.

DETROIT.

In using the snare for the removal of aural polypi, it often has to be rethreaded several times during a single sitting, a procedure which is always more or less tedious or annoying. I have devised a loop with the ends of the wire twisted so that it may be inserted into any snare with a single open canula with very little trouble. A piece of malleable steel wire No.

36 or 40 (about a foot in length for the Blake snare) is doubled and twisted (best in a small lathe, holding the loop end between the fingers), leaving the loop of any desired size. These loops are so very easy to make that they are inexpensive, and may be made up and kept on hand in sufficient numbers to have them always ready.

32 West Adams Avenue.

Medical Organization.

How to Encourage Scientific Work in County Societies.

The enthusiasm with which the work of organization is being taken up all over the country is certainly most encouraging, and it is not the time to throw cold water to cool off this enthusiasm. And yet it is the time to call attention to the fact that the work may all come to naught if we do not recognize the necessity of doing something to keep the majority of the county societies from becoming dormant, if not extinct, by making them of practical value to their members. The necessity of assistance from those outside of a county, in the creation of county societies, is now happily recognized and acted on by most of the state bodies. It must also be recognized that if these societies are to be made useful the same outside assistance must be kept up. Spasmodic efforts at organizing societies have been going on for years, and these have been temporarily successful. But once organized the weaker—and not seldom even the stronger ones—sooner or later died out.

The gardener who plants a flower and neither waters nor cultivates it would be considered very foolish. The flower might grow if the soil and environment were right.

There are various ways in which a society may be made advantageous to its members, and one of the most important is that it shall be of benefit as an educational institution and as a help in scientific work. It is in this that the state society should recognize its first duty. When the profession is well organized and the machinery for such work is completed, we may hope to see undertaken a sort of post-graduate work, something on the plan of the university extension movement, modified, of course—of which more in the future. At the present time, however, the adoption of some such work as outlined in these columns last week by Dr. Leartus Connor, should be immediately undertaken. In those states that have already organized, and have adopted the councilor system, this work should be undertaken by the councilors, and without waiting for instructions from the state body. It is their duty to assist in and help make effective the scientific functions of the county society. And in no simpler or more economical way can they do this than by getting these bodies to invite outsiders to aid them by reading papers, etc. The councilors should co-operate by getting volunteers to prepare papers on subjects of practical interest. There will be no trouble to get men to do this, and undoubtedly the societies would gladly welcome such outside aid in making their meetings interesting. There would be no objection to one read-

ing the same paper to a half a dozen or to a score of societies, and thus such a one would be encouraged to spend time in preparing something good to present. The invitation to take part in this work should not be limited to men with a reputation or to those living in a populous center, but, on the other hand, the country practitioner would in some respects be better. Let it be a mutual exchange of talent.

There is no need of argument to prove the advantage of such work. The more successful societies are doing it to-day. The largest county society in the country, the Chicago—Cook County—Medical Society, every few weeks invites men from other parts to read papers. Flourishing societies in Boston, New York, Philadelphia, Buffalo, Cleveland, Cincinnati and other large centers are continually inviting outsiders, and find it an attractive feature, but above all it brings new ideas, new inspirations. How much more is this needed in the smaller societies in the country districts! In societies of only twenty or thirty members—and not a third willing to prepare good papers—the necessity for outside inspiration is surely recognized by all. Even in the society with good workers the monotony of meeting the same men and hearing the same subjects discussed from the narrow viewpoint of a single locality is bound to result in a gradually decreasing attendance, and finally in total failure.

We sincerely hope that the councilors will take this matter up, individually if not collectively. In the states which have not reorganized, a "Committee on Scientific Work" should be created. But even in these states the president or secretary of the state society can take this work on himself; he need not fear to undertake it even if he has not been ordered to do so.

Let the good work begin now.

Medical Defense.

While we believe that there are functions belonging to medical organizations of more immediate consequence than the defense of its members against malpractice suits, nevertheless this is a matter of decided importance, and we are therefore glad to note that both state and county societies are taking it up. At the recent meeting of the New York State Medical Association that body adopted resolutions endorsing medical defense by its county branches. The Chicago Medical Society has a committee at work looking to the adoption of medical defense as one of its functions. The Philadelphia County Medical Society at its last meeting took up the work and adopted the following amendment to its constitution:

FOR MEDICAL DEFENSE.

Section 1. Within 15 days after the business meeting in January, the Board of Directors shall appoint an attorney-at-law for the term of one year, who, in addition to representing this society in and threats against its members as herein-
and the District Attorney in prosecuting ille-
and representing this society in other

ance with the conditions hereinafter named, assume the defense of suits for alleged malpractice brought against members of this society.

Sec. 3. The Board of Directors shall not undertake the defense of any suit based upon acts prior to the qualification of the accused as a member of this society.

Sec. 4. Any member desiring to avail himself of the provisions of this article shall first present his case to the Board of Censors, who shall decide upon the validity of the claim. He then may make application to the Board of Directors through the Secretary, shall sign a contract renouncing his own and vesting in the Board of Directors sole authority to conduct the defense of said suit, and shall make such other agreements as the Board of Directors may require. Provided, that nothing in the foregoing shall conflict with united action in the defense by the officials of any corporation organized for this specific purpose, with which a member may be connected.

Sec. 5. The Board of Directors shall thereupon contract with said applicant to take full charge of said suit, to furnish all necessary legal services, to furnish all medical expert services and to pay all necessary expenses of the accused. Provided, that if the accused is insured in a corporation organized for the legal and financial defense of physicians, the foregoing responsibility of the Board of Directors may be divided with said corporation. The Board of Directors shall not obligate the society to the payment of any damages awarded by decree of court or on compromise.

Sec. 6. The Board of Directors shall have authority to name the sum for the compensation of the attorney.

Western Central Medical County and District Society.

Physicians of Stevens, Big Stone, Wilkin, Traverse and Pope counties (Minn.) met at Morris, Minn., October 24 for the purpose of organizing a district medical society as a branch of the state society. Dr. Herbert L. Hulburd, Morris, was chosen president; Dr. Charles Christenson, Starbuck, vice-

president; Dr. Charles Bolsta, Ortonville, secretary, and Dr. James R. Elsey, Chokio, treasurer. The meetings will be held quarterly, the next one being held in Morris on the second Wednesday of January, 1903.

Genesee County (Mich.) Medical Society.

This society was organized October 28 at a meeting of physicians of the county held at Oak Grove Hospital, Flint, as a branch of the Michigan State Medical Society. Twenty-three physicians were enrolled as members and there were also in attendance two delegates from the Oakland County Medical Society. The following officers were elected: Dr. Charles S. Wheeler, Flushing, president; Dr. Lynch, Flint, vice-president, and Dr. Henry R. Niles, Flint, secretary and treasurer.

Gratiot County (Mich.) Medical Society.

About fifteen physicians of the county met at Alma October 30 and organized this society, to be a branch of the Michigan State Medical Society. Dr. Albert E. Bulson, Jackson, president of the state society, and Drs. Leartus Conner, of Detroit, and William T. Dodge, Big Rapids, members of the council of the state society, were present and assisted in the organization. Dr. George F. Butler, Alma, was elected president; Dr. Stiles Kennedy, St. Louis, vice-president, and Dr. Willard M. Weller, Ithaca, secretary and treasurer. Drs. Kennedy, Scott and Brainerd were appointed to draft a constitution and by-laws.

Nebraska.

At the last meeting of the Nebraska State Medical Society the matter of organization was discussed, but nothing could be done from the fact that the constitution could not be amended without the matter laying over for a year. However, a committee was appointed to revise the constitution and by-laws in accordance with the plan recommended by the American Medical Association, and also to take preliminary steps in organizing, if in the judgment of the committee it was thought best. This committee met November 6, at Omaha, and, after a thorough study of the work and a conference with members of the profession outside of the committee, it was decided to recommend the adoption of the Constitution and By-laws for State Societies prepared by the Committee on Organization of the American Medical Association, with certain minor modifications.

The work of organization has been taken up in several counties, although not as yet systematically. The Lincoln Medical Society, which for some years has been in a semi-dormant condition, recently passed a resolution to disband, provided a county organization was created. On November 4, the Lancaster County Medical Society was organized, to take the place of the Lincoln Medical Society. Over half of the physicians of the city and county joined at this first meeting, and it is expected that soon practically all of the eligible physicians of the county will be members of the county society.

On Tuesday of this week the Omaha Medical Society was to consider the advisability of changing its name so as to make it a county society and to reorganize.

Societies.

COMING MEETINGS.

Indian Territory Medical Association, Muskogee, Dec. 2-3, 1902.
Western Surgical and Gynecological Association, St. Joseph, Mo., Dec. 29, 1902.

Upper Des Moines Medical Society.—The next meeting of this society will be held at Estherville, Iowa, in February, 1903.

New York Celtic Medical Society.—This society, at its recent annual meeting, elected Dr. Thomas F. Reilly president, Dr. John J. McCoy secretary, and Dr. Michael C. O'Brien treasurer.

Asociacion Medica de Puerto Rico.—The medical men of the island met at San Juan, September 21, and formed this association, with Dr. M. Quevedo Baez, president; Dr. Jose N. Carbonell, secretary, and Dr. Rafael Valez y Lopez, trustee, all of San Juan.

Union District Medical Society.—This society met at Hamilton, Ohio, October 25, and elected Dr. William S. Alexander, Oxford, Ohio, president, and Dr. Walter D. Hancock,

Millville, Ohio, secretary and treasurer. The meeting for 1903 is to be held in Rushville, Ind.

Southern Kentucky Medical Association.—This association, which met at Hopkinsville, October 24, before adjourning, to meet next year at Bowling Green, elected Dr. Frank M. Stites, Hopkinsville, president; Dr. William W. Ray, Hopkinsville, vice-president, and Dr. Lee P. Trabue, Elkton, secretary-treasurer.

Buffalo General Hospital Alumni Association.—The ex-interns of the Buffalo General Hospital met at the Hotel Niagara recently and formed an alumni association. After a banquet, officers were elected as follows: President, Dr. DeVillo W. Harrington; vice-president, Dr. Peter W. Van Peyma; secretary-treasurer, Dr. William I. Thornton, and executive committee, Drs. Thomas B. Carpenter, Edgar R. McGuire, and Edwin R. Gould, all of Buffalo.

Tri-County (N. J.) Medical Society.—The fourth annual meeting and banquet of this society, which includes in its territory the counties of Wayne, Sussex and Morris, was held at Washington, October 14. The following officers were elected: Dr. Theophilus H. Address, Sparta, president; Drs. Isaiah W. Condict, Dover, and John C. Johnson, Blairstown, vice-presidents; Dr. Charles B. Smith, Washington, secretary, and Dr. Frederick W. Flagge, Rockaway, treasurer.

Albany American Academy of Medicine Club.—A division of the American Academy of Medicine was formed in Albany, October 29. Dr. Charles McIntire of Easton, Pa., the president of the academy, explained the scope and functions of the academy. During the evening a local division was organized by the election of Dr. James F. Barker as permanent president and Dr. Charles M. Culver as permanent secretary, who are constituted the executive committee with power to act. This is the first permanent division to be organized in America.

NORTHWEST MEDICAL SOCIETY OF PHILADELPHIA.

Monthly Meeting, held Oct. 7, 1902.

The President, Dr. Wendell Reber, in the Chair.

Post-Diphtheritic Paralysis Affecting the Nose and Throat.

DR. CARLE LEE FELT read this paper, in which he divided the causal factors into three groups: the bacilli, the toxin and a by-product, the action of which is limited to the nerve tissue, called "toxone," the latter agent being accredited to Dr. Dundas Grant with being responsible for the paralyzes following the mild diphtheritic cases treated with antitoxin. The condition *per se* may also be considered under three headings: 1. Muscle degeneration. 2. Localized neuritis and degeneration. 3. Central nervous destruction and degeneration.

The most frequent site of this condition is the pharynx, 40 per cent. of the cases being confined to this region, and in 12 per cent. the palate and eye muscles are affected, while the muscles of mastication are very rarely involved or the senses of taste, hearing and smell impaired. The location of the membrane would seem to have very little influence over the extent of the paralysis. From observations made by Woodhead on 1,362 cases of post-diphtheritic paralyzes, the time of the onset of the disease would seem to be from 4 to 55 days, varying from 5 to 55 in the palate; 4 to 17 in the ocular-motor muscles; 5 to 10 in the heart, and 10 to 14 in other parts of the body, the duration extending from a few days to months and in rare instances no recovery taking place. The restoration of function depends on the nature and extent of the damage and the treatment of the case, the latter of which may be divided into preventive and curative measures.

That antitoxin prevents and does not cause paralysis is now generally conceded, and this opinion is borne out by the experiments on the lower animals. The ideal method of using this remedy is to inject it at the time the disease is acquired in a sufficient amount to completely neutralize the patient, but even this will not prevent the paralyzes caused by streptococcal infection, which is so often present. Strychnin, electricity, tonic baths, general massage, rest in bed, nutritious and easily assimilated diet and treatment tending to secure perfect action of the skin, kidneys and bowels are valuable adjuncts in the treatment of these conditions, but the use of local antiseptics was not thought to be of much import.

Post-Diphtheritic Paralysis Affecting the General Nervous System.

DR. LUTHER C. PETER stated that the frequency of the palsies is in direct proportion to the severity of the general infection, notwithstanding that occasionally a severe paralysis may follow a mild diphtheria. The most important etiologic factors are age and the location of the membrane, Gowers claiming that the largest per cent. of cases occur in adults, while the experience of other observers tend to a contrary opinion, the latter holding that most of the cases occur between the ages of 5 and 6 years. From the observations by Myers, it would appear that about one-fifth of the cases are followed by paralysis. That the paralysis may involve almost any portion of the body, particularly the nerves, spinal cord and brain; and muscles, especially the myocardium, is now pretty generally recognized, as is also the fact that the condition is caused by a toxin elaborated in the body by a diphtheria bacilli, the blood stream acting as a conveyance for the toxic agent. The localization of the paralysis can no doubt be explained by the proximity of the affected organ to the source of infection. Diversity of opinion exists as to whether the primary seat of the lesion is in the peripheral nerve or in the cord, and the more conservative view would seem to be that the entire neuron is pathologically affected, the change being perceptible only in the peripheral nerve.

The symptoms usually noticed during the second or third week of the attack, when convalescence has been fairly established, are progressive loss of strength, and wasting of the muscles of the extremities and trunk, if the latter is involved. In other cases, after the patient is up, may be observed regurgitation of liquids through the nose, nasal twang of the voice and difficulty in walking, which may terminate in the patient becoming bedridden, with loss of control of the bladder and bowels and paralysis of the respiratory muscles and heart. The knee-jerks are always affected, and their absence has been noted in all cases of diphtheria, with or without paralysis. Usually, however, the disease is not so severe, and is generally completely cured by four to eight weeks of rational treatment. Instead of being general the paralysis may be localized, in order of the frequency of their occurrence being palatal, ocular, cardiac and diaphragmatic. The cardiac affection is now thought to be secondary at least to functional disturbance of the vagi and possibly due to organic changes in the nerve structure, being most frequent between the ages of two and nine years and occurring from the second to the thirty-sixth day of the disease, the symptoms indicative of its onset being cardiac irregularity, bradycardia, tachycardia, a lowering of the temperature and vomiting. Eighty per cent. of the fatalities following post-diphtheritic paralysis are due to this variety of the disease. Diaphragmatic paralysis furnishes about 13.7 per cent. of the fatalities, occurring principally between 2 and 6 years of age, the symptoms being dyspnea, retraction of the upper abdomen during inspiration, weakness of the voice and a tendency to the accumulation of mucus in the trachea and bronchial tubes.

The important factors in the differential diagnosis of the condition are the history of a previous attack of diphtheria, the conditions present at the onset of the attack, the extent of the wasting, and in the cerebral type the preceding convulsion. The prognosis is usually good, the greatest mortality being in the cardiac and diaphragmatic cases.

In regard to treatment, antitoxin was thought to be the first and foremost remedy, its value as a preventive being fully established by the experiments of Rainy on guinea-pigs. Absolute rest in bed during the primary disease was considered imperative, and many of the cases of paralysis were felt to be due to premature activity on the part of the patient. The use of iron and strychnia internally, and in the cardiac cases of strychnia hypodermatically, was thought to be important.

Post-Diphtheritic Ocular Paralysis.

DR. P. N. K. SCHWEYK read a paper, in which he stated that the post-latent stage of diphtheria is almost invariably characterized by ocular paralysis. Few muscles are usually affected at the same time, the ciliary muscles being the most

commonly and the sphincter muscles the most rarely affected. Post-diphtheritic ocular paralysis is usually bilateral. Paralysis of the sphincter irides is rare.

These attacks are usually observed in from two to six weeks after the attack of diphtheria, and require about the same length of time for a cure, the prognosis being more favorable in the young than in the older patient. There is an inability to distinguish near objects and double vision may or may not be present. The severity of the primary disease bears no relation to the ocular paralysis, and in the author's opinion the condition is produced by the action of the toxins on the peripheral nerve centers.

Discussion.

DR. CHARLES W. BURR believed the chief causative factor in these cases of diphtheritic paralysis was multiple neurosis. Regarding prognosis, the most important factor to determine is whether it is a multiple neuritis or a cerebral affection, in the former case the prognosis being very good, while in the latter it is very poor. The most important feature in the treatment is absolute rest.

DR. R. W. BEMIS did not believe antitoxin should be used to the exclusion of everything else, as he felt that muscle changes take place as soon as the local manifestations are visible, thus the antitoxin can not be given early enough to secure the effect which is produced in the experiments on guinea-pigs, in which the diphtheritic toxin is injected and immediately followed by an injection of antitoxin. While he believed that antitoxin was an important factor in the cure of diphtheria itself, he felt that it had but little effect on the paralysis.

TRI-STATE MEDICAL ASSOCIATION OF ALABAMA, GEORGIA AND TENNESSEE.

Fourteenth Annual Meeting, held in Birmingham, Ala., October 7 to 9, 1902.

The President, Dr. John C. La Grande, Birmingham, in the Chair.

Welcome.

The delegates were welcomed to Birmingham by Mayor W. M. Drennen. On behalf of the Jefferson County Medical Society the association was welcomed by Dr. R. M. Cunningham, Big Sandy, Tenn., representing Dr. Cunningham Wilson, president of the county society, who was prevented from being present by illness.

Sociology.

The first day's sessions were taken up with sociologic questions.

DR. C. F. DOUGLASS, Douglassville, Ga., spoke of "Sociology and Industry." He descanted especially on the question of insobriety and presented arguments on the evil effects of alcohol and the methods of obviating this evil.

DR. DAVID L. WILKINSON, Montevallo, in a paper entitled "Some Further Remarks on the Medical Supervision of the Education of Boys and Girls," recommended that there be a physician on every educational board with a salary sufficiently large to warrant him in devoting a considerable portion of his time in looking after the health of the children.

DR. LOUIS EDELMANN, Huntsville, Ala., caused a good deal of discussion by his paper on "The Negro as a Criminal and His Influence on the White Race." The author stated that the negro had a great influence over the white race, and that as a whole it was for the bad, and argued that the state should have a farm and should rigidly enforce the vagrant law compelling all negroes without work to go to the farm. The statements of the chiefs of police of the south that there were three negro criminals to one white criminal were given by the author, who also urged the establishment of a reformatory for the children of both white and colored races as a preventive of crime.

PROF. JOEL DU BOSE, Birmingham, read a paper on "Dynamic Sociology," and the symposium closed with a paper on "Crime and Its Causes," by Dr. Hugh L. Appleton, Center, Ala.

The annual banquet was attended by about 200 physicians, Dr. John C. La Grande, Birmingham, presiding as toastmaster.

Election of Officers.

The following officers were elected for the ensuing year: President, Dr. Michael Hoke, Atlanta, Ga.; vice-presidents, Drs. Cola H. Peete, Macon, Ga.; William L. Nolen, Chattanooga, Tenn., and Lewis C. Morris, Birmingham, Ala.; secretary (re-elected), Dr. F. Trester Smith, Chattanooga, Tenn., and treasurer, Dr. George R. West, Chattanooga, Tenn.

Tuberculosis Congress.

The following resolution was presented and adopted by the society: "*Resolved*, That this society endorse the object and aims of the American Congress on Tuberculosis to meet in St. Louis, in July, 1904." Drs. Seale Harris, Union Springs, Ala.; Robert H. Tatom, Chattanooga, Tenn., and Cola H. Peete, Macon, Ga., were appointed delegates to represent the society at the congress.

Revision of Constitution.

A committee of three, consisting of Drs. Willis F. Westmoreland, Atlanta, Ga.; William G. Harrison, Talladega, Ala., and Frank Trester Smith, Chattanooga, Tenn., were appointed to revise the constitution.

For Good Roads.

In order to show the interest the medical men are taking in the matter of good roads the following resolutions were passed:

Resolved, That the members of the Tri-State Medical Association of Alabama, Georgia and Tennessee are very much interested in the building of better roads in the states represented by this association.

2. That we urge this community to lend every support possible to the good roads convention of north Alabama, which is to meet October 2 in this city.

3. That this medical association will lend any aid possible to the convention referred to.

4. That a copy of these resolutions be sent to the secretary of the goods roads convention in north Alabama.

The convention decided to meet next year in Atlanta, Ga.

SOUTHERN TRI-STATE MEDICAL ASSOCIATION.

*Third Annual Convention, held in Dallas, Texas,
October 7 and 8, 1902.*

The President, Dr. John S. Turner, Terrell, Texas, in the Chair.

Education of Feeble-Minded Children.

DR. CHARLES T. WILBUR, Kalamazoo, Mich., by invitation, read a paper on this subject, in which he said that he considered the proper education of feeble-minded children one of the most important subjects before the medical world to-day. Each state should take care of its children of feeble mind and should have a place especially adapted for their education. The most suitable place for an institution of this kind would be in the country, where the children can obtain the advantage of fresh air and exercise. They should be taught to beautify the grounds, cultivate the farms, and should also be taught the higher branches of education as these serve to influence the mind toward nobler things. From an institution of this kind the state could turn out citizens of the best kind, and instead of being a care to the public all their lives, they would be able to take care of themselves.

Medical Legislation.

In a discussion of the paper by Dr. James Orr, Terrell, Texas, on "The Medical Profession and Medical Legislation," Dr. Samuel E. Milliken, Dallas, urged the importance of the association adopting a constitution in accord with that of the American Medical Association, and Dr. Frank Paschal, San Antonio, Texas, expressed himself as heartily in favor of a state board of health, but said that he did not believe in allowing legislators to make laws relating to the medical profession when the legislators did not understand the first principles of the medical profession.

President's Address.

The retiring president, Dr. John S. Turner, Terrell, Texas, in his annual address, spoke of men who had greatly benefited humanity by research in the field of medicine and of the great advance that had been made in that field in the past few years.

Election of Officers.

The following officers were elected for the ensuing year: President, Dr. James C. Loggins, Ennis, Texas; vice-presidents, Drs. R. J. Grabill, South McAlester, Ind. Ter.; Joseph B. Relater, Oklahoma City, Okla., and Frank Paschal, San Antonio, Texas; secretary and treasurer, Dr. Charles M. Rosser, Dallas, Texas.

CONFERENCE OF STATE AND PROVINCIAL BOARDS OF HEALTH OF NORTH AMERICA.

*Seventeenth Annual Meeting, held at New Haven, Conn.,
Oct. 28 and 29, 1902.*

Under the Presidency of Dr. H. M. Bracken, Minneapolis.

(Continued from page 1203.)

Summer Resorts.

DR. C. A. LINDSLEY, New Haven, Conn., read a paper, treating this subject under the following heads: The tented camp; the million dollar hotel; the variety of guests who are entertained at them; their temporary occupation; the brevity of the visits of the great majority of those who frequent them, and their sense of responsibility while being there; the enormous increase of population when the summer influx is compared with the permanent residents of the remainder of the year; the colonies of cottages clustered in close proximity and the risk of unsafe results to health from all these peculiar conditions.

Quarantine Against Yellow Fever in Cuba.

This paper was read by MAJOR W. C. GORGAS, U. S. A. He described the quarantine methods in use during 1901.

Early in 1901, the army board put forward the theory which they had demonstrated, and which Dr. Finlay had, for the past twenty years, maintained, that the mosquito was the means by which yellow fever was conveyed from patient to patient, and the only means, and that it was not conveyed by fomites and articles soiled by the yellow fever patient. As the result of the acceptance of this theory by the sanitary department, changes were made in the quarantine regulations. If the disease could only be transmitted from a sick person by a mosquito, there would be no occasion to give any care to the bedding, fabrics, etc., soiled by the sick person, or that from the infected locality. In accordance with this view, the quarantine regulations of the city were modified. When a case was reported as yellow fever, the quarantined area was at once screened at public expense, with the idea of keeping infected mosquitoes in, and of keeping out all mosquitoes that had not been affected. When the case terminated, all the mosquitoes were killed by fumigation with pyrethrum powder, but no attention was given to clothing, fabrics, etc. Sulphur, tobacco and other substances are very much more deadly to the mosquito, but it was feared that if the people were caused too much inconvenience, it would result in cases being concealed, and this would defeat the success of the work.

The author believes that under the system of inspection, as enforced in Havana during 1901, yellow fever would no more frequently get into the United States than it has during the past year of rigid quarantine. The relief to commerce under such a system would be enormous. With present knowledge and experience he advocated as a quarantine against yellow fever, both land and maritime, that infected vessels, or vessels coming from an infected port, be carefully fumigated, so as to kill all mosquitoes in every part of the vessel. This would apply to ships on water and all cars, etc., on land. That the passage of merchandise, baggage, etc., be interfered with in no way whatever. That passengers, when sick, be quarantined and isolated; that all other passengers be allowed to pass freely; that non-immunes from infected points be seen once a day by a medical inspector, and if at the end of five or six days they are well, that they be released from all surveillance.

Method of Stamping Out Yellow Fever Suggested Since 1899.

DR. CHAS. J. FINLAY, Havana, Cuba, contributed a paper on this subject. His conclusions were:

1. That the germ of yellow fever is only pathogenous for human beings when introduced by inoculation.

2. That the regular process by which the inoculation of a germ is accomplished in nature is through the bites of the *Stegomyia fasciata*, the insect having previously become contaminated through the act of biting yellow fever patients within the first five or six days of their attack.

3. That, although the bites of a recently-contaminated mosquito can only produce a mild attack of yellow fever or simply confer latent immunity without eliciting any pathogenic reaction, the bites of the same insect, when its contamination dates back from several days or weeks, may be expected to produce severe or fatal attacks of yellow fever.

4. That the yellow fever mosquitoes, after they have once been contaminated, retain the power of inoculating the disease during the rest of their lives if they have chances of biting non-immunes.

5. That the essential conditions for stamping out yellow fever from an infected locality are: (a) to protect yellow fever patients from the bites of the special yellow fever mosquitoes; (b) to destroy all mosquitoes which may have reached yellow fever patients; (c) not to allow non-immunes to enter the infected zone until the last of the contaminated insects may be supposed to have died; (d) to lessen the chances of propagation by adopting adequate measures calculated to prevent the multiplication of mosquitoes in general.

6. In 1898, when the author reckoned the longevity of the stegomyia at thirty-five to forty days, as a maximum, he fancied that his theory would be improved by including also the possibility that the infected insects might transmit their infection to their progeny, as the cattle-tick is supposed to do with regard to Texas fever. The reasons which induced him to make that suggestion ceased to exist from the moment that the United States commission proved that some of the stegomyias live as many as seventy or more days, and the author was not sorry to give up an idea which did not fit readily his theory.

No Decision on Yellow Fever Propagation.

MAJOR W. C. GORGAS presented the following resolution as the report of the committee on yellow fever resolutions signed by Drs. Gorgas, Ross and Glennan:

Resolved, That in view of the establishment of the fact that yellow fever is only transmitted by the mosquito, this conference is of the opinion that there is no longer necessity for the disinfection in yellow fever cases of clothing, bedding, fabrics, or effects of any kind, but simply to take measures looking to the control of the sick and the extermination of infected mosquitoes. In cases where non-immunes have been exposed to infection, they should be observed during the period of incubation.

DR. J. S. STEPHENS, Natchitoches, La., representing Dr. Arthur Nolte, of the Louisiana State Board of Health, submitted a minority report, to the effect that the mosquito was not the only mode of transmission of yellow fever, he and his confrères believing that fomites carry the disease. The experience in the past had been extensive in that regard. Believing, therefore, that both the mosquito and fomites were modes of transmission of the disease, in Louisiana the same quarantine was maintained to-day that was carried out years ago, with slight modification.

After a spirited discussion, participated in by several members of the Conference, Dr. John S. Fulton, Baltimore, moved that both the majority and minority reports be spread on the proceedings, but that the conference not commit itself to any expression concerning the practical measures to be used in restricting yellow fever. This motion was adopted.

Address of Welcome.

An address of welcome was delivered by Prof. Wm. H. Brewer, president of the State Board of Health of Connecticut, after which came the delivery of the presidential address, by Dr. H. M. Bracken, Minneapolis.

The State in Its Relation to the Tuberculous.

DR. BRACKEN considered the subject under the following heads:

1. The care of the advanced or incurable cases.
2. The care of the incipient cases.
3. The protection of the uninfected.

Humanity demands that we should care for the incurable individuals. The last United States census gives the total number of deaths during the census year from this one disease as about 110,000. Undoubtedly, a large proportion of these patients were too poor to care for themselves during the latter part of their illness. Looked at from an economical standpoint, it is wise to provide special hospitals for such cases rather than to thrust them on the general hospitals where they may infect the non-tuberculous patients. Humanity demands that the tuberculous poor should be decently housed. Discretion, as well as humanity, demands that the incurable tuberculous shall be properly cared for.

The present method in vogue in certain state institutions of drawing a line between the advanced and the incipient cases of tuberculosis, and saying to the former, "Go hence; we can not cure you; we do not want you; you can not get well; go home and die, while we care for those only who may recover," is highly deplorable. It is depressing; it is inhuman. Undoubtedly a percentage of the advanced tuberculous cases may recover. Why should this class of patients be told, indirectly at least, that they are incurable? Why should not hope be held out to them as long as there is any hope whatever?

The incipient tuberculous demand attention. It is easier to persuade legislators to give money to institutions that can show great results. Every hospital is ambitious to keep its death rate as low as possible. Appeals for institutions for the incipient tuberculous are influenced by the fact that better results can be shown for this class than for the advanced cases, and the feeling prevails that it is through results we must appeal to legislators.

If it is a public responsibility to provide for all tuberculous individuals, it is an imperative duty to protect the non-tuberculous. This can only be done by removing all tuberculous individuals from the homes or places of residence where they are a source of danger.

DR. BRACKEN presented resolutions, which were adopted, declaring the conference in favor of notification and registration of the tuberculous, and that state and municipal authorities should care for such individuals and provide proper institutions for them.

California Plague Situation Condemned.

PROF. F. C. ROBINSON, Brunswick, Maine, presented the following resolutions in behalf of the State Board of Health of Maine, expressing the opinion of the conference as to the conduct of the health authorities of San Francisco in dealing with the plague question:

WHEREAS, Thirty cases of yellow fever have occurred since July 13, 1902, to their origin or exact location having been steps having been taken to restrict the City Board of Health of San Francisco being a sides of the State Board of Health of California having been fully established by the history, supported by documentary evidence in the possession of this conference; therefore, be it

Resolved, That the Conference of State and Provincial Boards of Health of North America views with abhorrence the irretrievable disgrace of the present State Board of Health of California, and pronounces the plague situation in California a matter of grave national concern; and be it further

Resolved, That the National Conference of State and Provincial Boards of Health of North America does hereby advise the various State Boards of Health of the United States to consider the propriety of calling on the Surgeon-General of the United States Public Health and Marine-Hospital Service to arrange at the earliest possible date a joint conference for the purpose of eradicating the plague from the United States.

The resolutions were unanimously adopted.

DR. CRESSY L. WILBUR of Lansing, Mich., read two papers, one entitled "Progress of the Movement for Uniform Statistics of Causes of Death," and the other, "How Shall Births Be Registered?"

Some Recent Evidence as to the Spread of Typhoid Fever.

DR. HENRY B. BAKER, Lansing, Mich., followed with a paper on this subject. In about 25 or 30 per cent. of the cases of typhoid fever, the urine contains vast numbers of the specific micro-organisms which cause the disease; also that this condition sometimes remains for a considerable time after apparent recovery, and that cystitis months after recovery from the fever may be due to the continued presence of typhoid bacilli in the bladder. This is one reason why typhoid fever is sometimes spread more or less directly from person to person, and

Practice of Medicine—Osteopathy—Use of Title.—Chapter 117 of the Laws of North Carolina of 1885 amended Section 3132 of the Code with regard to practicing without license by adding thereto: "And any person who shall begin the practice of medicine or surgery in this state for a fee or reward, after the passage of this act, without first having obtained license from said board of examiners, shall not only not be entitled to sue for or recover before any court any medical bill for services rendered in the practice of medicine or surgery, or any of the branches thereof, but shall also be guilty of a misdemeanor," etc. In the case of *State vs. McKnight* the question was the simple one, the Supreme Court of North Carolina says, whether one who practices "osteopathy" is indictable if he has not procured the license required for any one by the above section before beginning "the practice of medicine or surgery." A special verdict of the jury found that the defendant's "treatment of his patient did not consist in the administration of drugs or medicines, but in the manipulation, kneading, flexing and rubbing of the body of his patients and in the application of hot and cold baths, and in prescribing rules for diet and exercise; . . . that the defendant was engaged in the general practice of that science; that he also prescribed hypnotism and suggestion under hypnotism." It also found that "upon two occasions he used a small surgeon's knife in opening an abscess in the mouth of one Shedd, but charged no fee for his services." The Supreme Court says that all it can declare on the facts found in the special verdict is that the defendant's practice was not the practice of medicine or surgery, and no license from the medical board of examiners was required. It says that the only surgery was without fee or reward, an act of charity and that was incidental and not in the usual course of the practice of osteopathy. It can not be said that one practices "medicine and surgery" when he uses neither drugs, medicines or surgery. Section 3124 requires the "board of medical examiners" to examine all applicants, "to practice medicine or surgery in anatomy, physiology, surgery, pathology, medical hygiene, chemistry, pharmacy, materia medica, therapeutics, obstetrics and the practice of medicine." It can not be conceived that the legislature would require the above examination for a profession which eschews the use of drugs and surgery. As to the argument that the science, if it be a science, of osteopathy is an imposition, the court, legally speaking, knows nothing. It only knows that the practice of osteopathy "is not" the practice of medicine or surgery as is commonly understood, and therefore it is not necessary to have a license from the board of medical examiners before practicing it. If it is a fraud and imposition, and injury results, the osteopath is liable both socially and criminally. Doubtless there is an appeal to the imagination, but that is a necessary ingredient in all systems of healing. The aim of medical science, now probably the most progressive of all the professions, is simply to "assist nature." Osteopathy proposes to do that by other methods than by the use of medicines, or the surgeon's knife. Moreover, the court says that it attaches no weight to the argument that the defendant hung out his sign and advertised himself as "doctor." The special verdict found that he had a diploma from a college of osteopathy bestowing that title upon him. There are many kinds of doctors besides medicine—as doctors of law, doctors of divinity, doctors of physics and veterinary doctors and others still. Besides in this country, so far at least as titles go, "honors are easy." If the General Assembly shall deem osteopathy a legitimate calling it may see fit, possibly, to protect educated and skilled practitioners by requiring an examination and license by learned osteopaths of applicants for license, but certainly the examination would be on subjects appropriate to secure competency therein, and not on an entirely different course such as that prescribed for applicants to practice medicine and surgery. Dentistry is not the "practice of medicine or surgery," but it is a related profession, as is also pharmacy, and each has its prescribed course of examinations of applicants for license. Whether the same rights and dignity shall be bestowed on osteopathy is a matter for the general assembly, or if it is found to be a fraud, its exercise may be made indictable. It seems that it more nearly approximates nursing in many respects (though differing in others) when taught as a profession.

1. Colles' Fracture.—Fowler describes the various forms and conditions of Colles' fracture, which has no classical type, but varies from a slight separation of a spicula of bone to extensive fracture with large displacement or impacted fracture. He remarks that it is not correct to say that there is no deformity with impacted fracture. There is a relative downward displacement and a more or less pronounced radial flexion (abduction of the hand or forearm). Pain is often a prominent symptom. He remarks that in treatment, if sufficient force can be brought to bear to overcome the deformity at once, and if pains be taken to maintain the normal position of the ulnar nerve by a sufficiently hard and properly applied pad placed on the palmar side of the head of the ulnar, and if, in addition, early massage and movements of the fingers, both active and passive, be employed, the very best results can be obtained in the great majority of cases. He uses a tightly rolled portion of an ordinary muslin roller bandage about the diameter and length of the little finger, prevented from slipping by covering with pieces of adhesive plaster folded in such a way that before applied it presents an adhesive surface to the skin as well as to the roll. An anesthetic should always be employed and the normal length of the radius restored if possible. The ulna is then forced into place and the roll placed on the palmar surface to retain the reduction, and held there by several turns of adhesive plaster, the breadth of which corresponds to the length of the roll. The edges of the adhesive plaster are nicked to prevent these from sinking into the skin should swelling occur subsequently. The arm is placed in a sling with the

hand dependent, so as to maintain the latter in a position of ulnar abduction. In spite of every effort, however, it will be found impossible to effect a complete reduction in certain cases, but they are rare. Where the deformity resulting from failure to reduce the displaced ulna is of sufficient importance, either from impairment of function or the presence of pain or otherwise, he has practiced the removal of the head of the ulna through an incision made along its border. The operation is performed subperiosteally, the section of bone being made by the Gigli wire saw. Where the alignment of the radius is but slightly disturbed, the displacement of the lower fragment being entirely in the upward direction, and at the expense of its cancellous tissue into which the upper fragment is crushed, this operation will be found to fulfill all the indications of improvement of function, relief of pain and correction of deformity. Where the impaction is slight and shortening, due to an angular deformity or a bowing of the radius, it will not be so useful. Here nothing short of refracture with perhaps cuneiform osteotomy will completely serve the purpose. There are two symptoms, however, which excision of the head of the ulna will relieve. They are interference with palmar flexion of the wrist and the presence of pain.

2. See abstract in *THE JOURNAL* of October 18, p. 1000.

4. **Vertigo.**—The neurologic interest of vertigo is associated with disease of the brain and neuroses. Bailey mentions drug vertigo, and particularly in this connection that due to iodid of potash. He thinks it also occurs in the specific iodid treatment of suspected syphilis. In neurasthenia vertigo is principally subjective. The patients can walk a chalk line unfalteringly, and there is no increase in the normal swaying when they stand with the feet close together and the eyes closed. It is a symptom of fatigue and is intensified by idea. Some neurasthenics have real objective vertigo, and this should invite closer investigation as to whether due to degenerative changes of the blood vessels of the brain. In hysteria, vertigo is less frequently complained of, but there are a number of symptoms that might be mistaken for objective vertigo. In neither hysteria or neurasthenia is it possible to establish the nature of the vertigo by one symptom. In neurasthenia the diagnosis is by exclusion. Other causes must be eliminated before it can be set down as purely neurasthenic and functional. In organic diseases of the brain vertigo is due to interference with the centers of equilibrium in the medulla and cerebellum, and the author gives the connection of these with the ganglion of Scarpa in the internal ear and its connection with the semi-circular canals, explaining thus the phenomena. The medulla, pons, cerebellum and possibly the cerebrum are the nervous structures in which foci exist that may give rise to subjective and objective vertigo. In the pons and medulla such invasion is usually tumor, while in the cerebellum abscess is more frequent. Injuries may also cause loss of equilibrium in the cerebellum, but they are rare. When they occur in the medulla and pons they are usually rapidly fatal. It is in the cerebellum that vertigo as a focal symptom of nervous disease is of great importance. Cerebellar vertigo is essentially static and locomotor; in the prone position the patient is usually free from it and it is not made worse by closure of the eyes. Theoretically the staggering is toward the side of the lesion, but practically this is not always the case. The great difficulty in the diagnosis is due to pressure symptoms at a distance. He points out the difficulties in the localization of the lesion in the cerebellum, though the existence of cerebellar disease is not so difficult of diagnosis. Unless unilateral nerve deafness is present it is impossible to be certain as to which side is affected. It is also suggested as a possibility that the main centers of equilibrium may have their representations in the cortex. Two chronic brain diseases are especially notable for vertiginous symptoms: they are epilepsy and general paresis. Vertigo is a very frequent symptom, especially in the petit mal attacks. Cerebral endarteritis is one of the most fertile causes of vertigo due to brain disease, and is especially prominent in the aged. It is often the chief clinical symptom of general arteriosclerosis.

5. **Ocular Vertigo.**—Marple discusses the causes and symptoms of ocular vertigo, remarking that it is most frequently

due to paralysis or paresis of some nerve supplying the ocular muscles and causing diplopia. The less conspicuous the ocular anomaly the more apt is the patient to suffer from vertigo. Failure of the vertigo to disappear when one eye is closed does not necessarily exclude the possibility of some muscular anomaly of the eye. If closing one eye, the right for example, does not cause the disappearance of the vertigo, then have the patient close the other eye, that is, the left alone. If we have to do with paralysis or paresis of the ocular muscles the vertigo will disappear at once. As to what muscle is affected it is often very difficult to decide, but this is only of interest to the ophthalmologist. The causes of ocular paresis are chiefly syphilis, diphtheria and diseases of the brain and cord, and the treatment should be that of the underlying cause. If we have excluded any paralytic muscular anomaly, the chances of finding any ocular cause for the vertigo are much lessened. If there is any ocular paralysis he thinks it improbable that the eyes are the cause of the vertigo. There should be a rigid examination made for refraction, under a mydriatic, if possible, and for the correction of any error that may exist. He remarks in conclusion that while he has met with a few cases of vertigo associated with ocular palsy, the number in which a muscular or refractive anomaly of the eye was the cause, has been very small.

7. **Ligation and Clamping the Ureter.**—The experience at the Johns Hopkins Hospital, including 16 cases, is reported and analyzed by Sampson. He concludes that occlusion of the ureter by a ligature or clamp is of quite frequent occurrence during gynecologic operations. Only a portion of these injuries are recognized either during operation or afterwards. A ligature about a ureter, if removed before the close of the operation, will probably do no injury. The clamp is more liable to give rise to post-operative results, but neither, if removed before the close of an operation, do as much harm as an operation that interferes with the blood supply of the ureter sufficiently to give rise to a urinary fistula, due to sloughing of the ureter at that place. Complete and permanent occlusion of the ureter in the absence of infection leads to renal atrophy, with more or less dilatation of the ureter and pelvis, usually without symptoms or evidence of constitutional disturbance, and probably without much shock. Ligation of the ureter is probably less likely to cause either a marked hydronephrosis or a pyonephrosis than a uretero-ureteral anastomosis. Ligation of the ureter may be considered a justifiable procedure when necessary in cases in which uretero-ureteral or ureterovesical anastomosis is impossible. Such operations, however, have been successful under great tension in which 2 to 9 cm. of the ureter had been removed. In ligation of the ureter care should be taken to doubly ligate it with non-absorbable material, and if possible to place the ligated end in a skin incision. Only a portion of the cases of ligation or clamping of the ureter can be recognized after operation as: 1. In cases in which both ureters have been occluded, anuria will probably be the only evidence of the trouble for the first twenty-four or forty-eight hours. 2. In cases where urinary fistula develops from injury. 3. Cases where definite symptoms arise, such as pain along the ureter and in the kidney region, possibly associated with chills and fever and other constitutional disturbances. These are exceptions rather than the rule and probably indicate a stenosis rather than an occlusion. 4. A mass may develop in the renal region due to formation of a hydronephrotic kidney, and this mass may form without symptoms. 5. The injury may be discovered at autopsy. Ligation of the ureter may terminate fatally when renal insufficiency exists or in cases of profound shock. A person in such a condition with only one working kidney has less chance than one with two. The ligature may slip, be absorbed, or in some way lead to leakage of urine, which, if the abdomen be closed and there be no avenue of escape, may cause death, especially if infection be present. Catheterization of the ureter preliminary to hysterectomy for carcinoma of the cervix is valuable in abdominal and combined abdominal and vaginal hysterectomies, but the catheter should be removed before closing the abdominal

cavity. The ureter can be palpated at any time, and therefore there is less danger of injuring it and the operation is expedited. Post-operative uretero-vaginal fistula from interference of the blood supply of the ureter is less likely to follow when the ureter is catheterized, for the exposure of that portion of the ureter above the broad ligament is unnecessary, as it can readily be palpated. If the ureter is adherent to the growth, the dissecting free of it would probably mean a return of the carcinoma, and also possibly a ureteral fistula due to interference with its blood supply. Hence it is better to make a wider dissection, excising the lower end of the ureter with the growth and implant the free end into the bladder, thus giving less chance for the return of the disease and also for ureteral fistula. The catheter itself protects the ureter in various ways, rendering its displacement a little more difficult. It is less likely to be kinked by ligation in the surrounding tissue. It also has other advantages; it prevents ligation doing harm by occlusion, and offers resistance to a knife or scissors, preventing the ureter being cut across, and helps in finding injuries to the ureter and also serves as a guide with which to repair the injury. Clamping the catheterized ureter may crush the catheter so that a portion of it will be left in the ureter in withdrawing the catheter; but this can readily be removed through a small slit and the slit repaired, hence the importance of withdrawing before closing the abdominal incision. If the catheterized ureter be clamped in a vaginal hysterectomy for carcinoma of the cervix, a portion may be broken off and left, which would probably necessitate an abdominal or retroperitoneal operation for its removal. While a catheterized ureter is easy to palpate in the vagina and hence its exact location may at any time be determined, the operator must always bear the foregoing in mind and determine its position before clamping. The author asks, is not vaginal hysterectomy for carcinoma of the cervix contraindicated when, according to Wertheim, in 90 cases of abdominal hysterectomy for carcinoma of the cervix, metastases of the carcinoma to the pelvic lymph glands were found in 30 of the cases, and there was no relation between the local extent of the disease and the presence or number of lymph glands involved?

8. Vertebral Arthropathy in Tabes.—Spiller reports a case of marked spinal deformity in tabes, a condition which had been noticed by Charcot and Marie and by Koenig, who considered the deformity due to fracture. He thinks possibly other cases may be found in the literature, but he reports it on account of its rarity.

9. Subcutaneous Tendon Splicing.—Rugh discusses the advantages and disadvantages of the open and the subcutaneous methods of operation on the tendons and offers a modified operation based on that of Anderson, who split a tendon longitudinally and slid one portion over the other and sutured in the position of correction. After having done this several times Rugh devised the following improvement, by which it can be done through a very small skin incision and without lifting the tendon from its bed. He uses a very small knife with a long shank and a blade about one and one-half inches in length, turned at right angle to the shank and having the cutting edge anteriorly so that, as the knife is pushed forward, the tendon is slit. After a thorough preparation of the skin the operation is done as follows: "The tendon is put on the stretch, and an incision one-half to three-quarters of an inch in length is made directly over it at about its middle point. After the tendon has been exposed, the blade of the knife mentioned is passed through its center, and being held on the same plane as the tendon, is pushed to the one extremity of the tendon, or for a distance of two or three inches, the tendon being outlined by the thumb and finger held on either side of it. The knife is then withdrawn in the same line, turned and pushed in the opposite direction for the same distance, thus splitting the tendon for four to six inches. The points at the upper and lower ends of the tendon to which the knife reached are marked on the skin with a sharp-pointed tenotome, and after withdrawal of the splitting knife the tenotome is introduced on the right side of the tendon at one end, and the right half of the tendon is severed by carefully cutting little by little

from above downward until the dividing slit is reached. When this half is severed it is seen to relax immediately, the tendon being held tense the while. Then the left half is cut in the same way at the opposite end and side, and as corrective pressure is made, the two halves slide past one another in the wound. When completely corrected, the two ends are sewed together through the small skin incision and the incision closed by one or two sutures. A plaster-of-paris or other fixed dressing is applied to maintain the correction secured, and this or another one worn for about four weeks, by which time firm union will have occurred." It will be readily seen, Rugh says, the most important objections to the Anderson method are overcome by this one, viz., the long skin incision, the danger of sepsis and that of sloughing from interference with the blood-supply. Like everything else, however, it has its disadvantages, but these have been found to be easily overcome. The first one is, the operation can not be easily performed in those cases in which the tendon has a partial twist, as the fibers do not run straight, and the splitting knife may run out at one side or the other. This condition, however, may be recognized so soon as the tendon is exposed, and if present the incision can then be extended and an Anderson operation done, without, however, lifting the tendon or separating it from its bed. If this is omitted, the circulation will be less disturbed, and consequently there will be less danger of sloughing. The second disadvantage is, there may be some uncertainty as to when the half of the tendon is severed, as a few fibers still remaining above or below may prevent relaxation of that half; but if the handle of a bistoury or other flat instrument be introduced into the slit, every fiber on the one side of this may be cut without danger to the integrity of the other half. He has done this operation in twelve cases with only satisfactory results, with no sepsis, a very small skin scar, definite lengthening, etc.

14.—See abstract in *THE JOURNAL* of July 12, p. 101.

15. Blood Condition in Burns.—After a rather full historical résumé, Locke gives an account of ten cases of severe burns observed in the Massachusetts General Hospital. His conclusions are: "1. The blood flows sluggishly, and is of a peculiar dark, purple appearance. 2. An immediate increase in the number of erythrocytes, in severe but not fatal cases, of from 1,000,000 to 2,000,000 per c. mm., takes place within a few hours; in fatal cases, of from 2,000,000 to 4,000,000 per c. mm. 3. A rapidly increasing leucocytosis constantly occurs: in cases ending in recovery often of 30,000 or 40,000 per c. mm.; in fatal cases usually above 50,000 per c. mm. 4. Morphological changes in the erythrocytes are slight. 5. The percentage of neutrophils is somewhat above the normal, but not so much as in the ordinary inflammatory leucocytosis. 6. A considerable destruction of the leucocytes takes place, especially in the very severe burns. 7. Myelocytes may be present in small numbers in severe cases. 8. There is, as a rule, marked increase in the number of blood plates."

16.—This article has appeared elsewhere. See *THE JOURNAL* of October 25, §36, p. 1072.

18. Tuberculosis.—Kime describes his method of treating tuberculosis by means of large reflectors throwing blue light, rich in actinic rays, over the chest, and reports 29 cases. He thinks the treatment with direct reflected light is much better than that from other sources. The human body is translucent to actinic light, and the irritant action of the light on the living body cells is a direct stimulus to them. A high percentage is absorbed by the tissues and produces definite chemical changes and also inhibits and destroys bacterial life.

19. Paraffin Prothesis.—From experiments with paraffin injections in rabbits Comstock concludes that it forms a sort of bridge-work in the tissues, and is not an encapsulated foreign body. He illustrates his paper with microscopic sections showing the results or differences produced after these injections and confirming his view.

20. Temperature.—Doty has examined a large number of emigrants at the New York Quarantine Inspection and finds that the average temperature is about as usually estimated, 98.5, but lower temperatures are very frequent, down to as low

as 96 or 97, especially early in the morning. A temperature above 99.5 he would consider pathologic. A higher temperature than normal may be due to nervousness, and often occurs this way in healthy individuals.

21. **X-Rays in Cancer.**—Grubbé reports cases and concludes that in properly selected cases the *x*-ray capable of producing remarkable results. The relief of pain is one of the most prominent features of the treatment. Restrictive changes are noticed in all primary cancer of tuberculous growth and the rays have a decided effect on internal cancer. The greatest result is obtained in treating post-operative cases to prevent recurrences. The proportion of clinical cures by this method is greater than that obtained by any other treatment. He maintains that there is an idiosyncrasy to the *x*-rays and the peculiarities of each case must be studied. Dermatitis within certain limits is sometimes a desirable feature in the treatment. The ordinary tubes with changing vacuums are not desirable for radiotherapeutic work, and only those which allow of perfect control of the vacuum should be used. The *x*-ray has a selective influence on the abnormal cells. It lessens hemorrhages and discharges and makes the patient more comfortable and prolongs life even in hopeless cases.

22. **Malaria.**—From his study of malaria in a California town Cadwallader has developed the theory that perhaps the increased proportion of water in the circulation may play a very important part in the causation of malaria, rendering the system more susceptible to infection.

24. **Nephritis in Smallpox.**—The following are the conclusions of Welch and Schamberg from a study of over 1000 examinations in 128 cases of smallpox with special reference to the kidney conditions: "1. Albuminuria is more common in smallpox than is generally believed, having been present in 65 per cent. of the cases examined. The fact that tube casts were found in 45 per cent. of the cases warrants the assertion that the albuminuria in most cases is the expression of a structural change in the kidneys. 2. Cases of discrete variola and well-marked varioloid have, in our experience, been accompanied with nephritis almost as often as cases with more profuse eruptions. This would suggest that the kidney involvement is the result of the influence of the smallpox poison. 3. The daily fluctuation in the presence of the abnormal urinary constituents necessitates repeated examinations in order to avoid misleading results. Microscopical examinations of the sediment will frequently reveal the presence of tube casts when albumin is not present in quantities demonstrable by the ordinary tests. 4. The clinical symptoms of variolous nephritis are, as a rule, mild and by no means as obvious as those observed in scarlatinal nephritis. 5. Arnaud's investigation demonstrates that albumin may persist in the urine in minute quantities after convalescence from smallpox. This occurred in 75 per cent. of his cases. The histological examination of the kidney would indicate that this minimal albuminuria represents interstitial changes in the kidney. 6. If it be true that the albuminuria accompanying infectious diseases is, in large part, the expression of a structural change in the kidneys, is it not probable that the damage thus done may, if unrecognized and uncared for, insidiously eventuate in chronic Bright's disease? 7. The practical lesson which is contained in this proposition is that the urine of patients convalescent from infectious diseases should be carefully and repeatedly examined and the diet and mode of life of the patient regulated accordingly.

31. **Uric Acid Diathesis.**—Croftan considers that of the primary cause of uric acid diathesis we know nothing, but he places himself on the neuro-humoral standpoint as defined by Duckworth. The neurosal element, while apparent, is intangible, essentially hereditary and probably not remediable in one generation. The perversions of the uric acid chemism are more definite and are amenable to considerable modification and to correction by dietetic treatment. The characteristics of uric acid diathesis are as follows: 1. The uric acid of the blood is increased. 2. Crystalline deposits of sodium urate are found in certain necrotic tissues. The increase of uric acid in the blood can be due to increased formation of uric acid,

which is usually in an analytic way from disassimilation of more complex compounds. The latest view is that uric acid is specific, a metabolic product of a special kind of albumin, namely, nucleins. These are the chief constituents of all cell nuclei and hence are contained in many articles of food and also in our tissues. The food nucleins we can control; the tissue nucleins we can not. The decreased destruction of uric acid is, the author thinks, a more prolific cause of uric acid accumulation than over-production. The retention of uric acid can not be definitely ascertained. The deposit of crystalline sodium urate in necrotic tissues must necessarily be due to local factors, probably poor vascularization of the parts may be made responsible to a large extent. The reduced alkalinity of the blood that has been credited is not demonstrated. A more important factor is change in the relative proportion of salts in solution in the serum. The significance of necrosis found in the vicinity of urate concretions is still obscure. As regards the dietetic treatment the two chief indications are: 1, to prevent the increase of uric acid in the blood; 2, to promote the solubility of uric acid either in the blood or in the concretions that have already formed. To reduce the production is one of the most feasible methods and the restriction of articles of food containing many cell nuclei must necessarily decrease the formation. The moderate use of uric acid forming food is rational treatment. We know too little of the normal mechanism of uric acid destruction to enable us satisfactorily to regulate this process, but certain dietetic rules can directly and indirectly aid in the elimination of uric acid by exercising an effect on the circulation and the renal excretion, indirectly, by sparing the heart and kidneys and enabling them to perform their function in a normal manner. Whether or not alkalies introduced into the system are capable of influencing the alkalinity of the blood and thus enhancing the solubility of urates is more than uncertain. But this is a popular belief and we may recognize that certain articles of food can increase alkalinity and others reduce it. Many foods contain alkaline salts, others acid salts of organic acids that are converted into carbonates in the body, and both impart an alkaline reaction to the urine. Sulphur and phosphorus in albumins are oxidized to sulphuric and phosphoric acids, and in this way reduce the alkalinity of the blood. We have also certain uric acid solvents, among them uric acid. Whether these will act in the blood stream as well as in the test tube remains to be determined. The following special rules are laid down: As regards the use of meat he thinks there is little difference between the so-called white and dark meats. Meats containing many cell nuclei, such as liver, kidneys, sweetbreads, brain, etc., and meat extracts, broths, gravies, etc., should be excluded. He holds that a certain amount of meat is necessary, while too much is bad. The digestibility of certain kinds must be considered. Eggs in moderation may be permitted, but he restricts the use of the yolk; the white has no effect on the uric acid increase. An exclusive milk diet is also bad in old people, but as an addition to a mixed diet is good if it can be borne. We must individualize. Its theoretical disadvantages are overcompensated by its highly nutritious character and its power to stimulate diuresis. On empiric grounds he excludes cheese from the dietary, though there is no compelling scientific reason for doing so. As regards fats there is no valid objection to their use in moderation. Carbohydrates have no appreciable effect on the uric acid increase, but their bulk and tendency to fermentation should be considered. They should be restricted, therefore, and in cases complicated with diabetes or obesity should be forbidden altogether or replaced by fats. In dyspepsia they should also be restricted, and in those inclined to overeat. These remarks apply to certain bulbous vegetables which contain a large amount of carbohydrate, but green vegetables, salads, etc., with the exception of young germinating plants like asparagus, may be given freely. Celery and onions are to be forbidden on account of the irritating oils they contain; tomatoes on account of the acids they incorporate. All spices and condiments should be avoided, as they irritate the digestive tract and overstimulate the appetite. All fruits, either deciduous or citrous, may be permitted. The crude

acids have no distinct effect on the increase of uric acid with the exception of tannic acid, which seems to increase it. Water should be the chief beverage, but not taken in excess; the flooding of the circulation with water is detrimental. The uric acid patient should drink one or two liters of water a day, no more or less, and it is better to take it in small quantities than in large quantities at long intervals. The uric acid solvent virtues of many mineral waters are problematical to the author. Tea, coffee and cocoa are generally forbidden and are to a certain degree restricted by him. Tea is preferable to coffee. Alcohol is generally to be forbidden on empirical grounds, except in some rare instances where the patients are accustomed to it. Champagne, sweet wines, cider, liquors and malted liquors are to be absolutely avoided. As in other dietetic treatment we should consider the previous habits of the patient, his temperament and character.

32. Cholelithiasis.—Weber treats the acute attacks of cholelithiasis with small hypodermics of morphin not less than one-quarter of a grain, a hot linseed poultice locally, a large enema to relieve and empty the rectum, and later, when nausea and vomiting have ceased, calomel or compound cathartic pills for thorough cleansing of the intestines. As regards olive oil by the mouth he has not been able to satisfy himself, but he has been in the habit of following up an acute attack of gall-stone colic by an enema of 4 to 6 ounces of warm olive oil high up in the bowel, to be retained over night and followed by copious flushing next morning with water, not soapsuds. The above described palliative treatment will not disappoint us so long as there is no manifestation of firm incarceration of one or more big calculi in the ducts of the viscus, and no empyema of the gall bladder. The paroxysm being over and when one is satisfied that there are only small concretions in the bladder, some of which have passed, he puts the patient on a proper diet, excluding all food rich in lime and magnesia salts, particularly peas, beans and certain cereals. The patient must eat sparingly, be very moderate in the use of alcohol, keep his bowels very regular and drink twice daily a half pint of hot Carlsbad water before eating. In cases of large gallstones crowding the ducts, the surgeon should be called in. Massage of the gall bladder has been recommended, but reflection shows that it is injurious. In chronic cases he found cases of solitary or large calculi in the gall bladder without enlargement of it, without icterus, but with chronic ailment which is altogether difficult to treat. Medical treatment, as a rule, does little good, and the surgeon must generally be called in. In a case of hydrops which caused but little pain, showed slight transient icterus, and was complicated with right floating kidney, he has seen good result from prolonged Carlsbad cure and the adjustment of the floating kidney. All chronic gall-stone disease, which never has severe attacks, or at least moderate relapses, requires careful supervision and treatment. He advises the use of alkaline waters and diet as above described at least twice a year and for four weeks at a time, in addition to this, hydrotherapeutic procedures like Turkish baths, etc.

33. Laryngeal Tuberculosis.—Levy has studied and discusses some 205 cases observed in Colorado, and finds that in cases in which both lung and throat lesions developed in Colorado, the latter showed itself at least forty-eight weeks later than in those originating elsewhere. In cases where the lung lesion developed elsewhere and the throat lesion in Colorado the throat lesion manifested itself on an average of 62.3 weeks later than those originating elsewhere. That is to say that as far as the development of laryngeal tuberculosis is concerned the effect of high altitude is to retard it by more than one year.

52. Normal Involution of the Appendix.—The fact first noticed by Senn and Ribbert, that the appendix normally undergoes an involution process marked by a disappearance of the mucous coat with obliteration of the lumen of the appendix, is discussed by Morris, who gives facts in his observation in regard to it. He notices the symptoms that seem to attend this involution and concludes that the solid replacement tissue is practically scar tissue, and that this scar tissue of the

appendix contracts and irritates nerve filaments that are involved in its extent. These produce sympathetic irritation of the intestinal plexuses, interference with their function and the various symptoms complained of. He says the symptoms accompanying normal involution of the appendix belong particularly to middle life, though they sometimes become marked as early as the twentieth year. The appendix usually feels harder than normal on palpation. The abdominal muscles are unnaturally resistant, protecting the irritated appendix very much as they do the infected one. He has seen the same symptoms to a large extent in tuberculosis of the organs. The treatment is symptomatic unless the disturbance is sufficient to call for removal.

53. Normal Saline Solution in the Abdomen.—Humiston gives an account of his method of using the peritoneal cavity as the inlet for large quantities of saline solution during abdominal operations. After partially closing the wound he pours into the cavity through a glass funnel not less than two quarts of normal saline solution at a temperature of 112 F. and quickly ties the few remaining sutures previously introduced. Within a few minutes the anesthetizer notes a change in the pulse, its rate diminishing, lowering tension and increasing fullness. The color of the face more nearly approaches the normal and usually the patients have little or no thirst for the first eighteen hours, have less pain, and require no enemata of any kind, and are thus kept free from the annoyance of too much nursing. In vaginal celiotomies where this method can not be employed he begins to have the saline administered subcutaneously, the trocar entering at the junction of the anterior axillary border at a line on a level with the upper border of the right breast, being plunged downward, backward and inward, so that the fluid finds the loose tissue in the axilla and backward underneath the scapula rather than under the breast. In this position, with a very little massage, three or four quarts can be injected with four feet of pressure. In emergency work outside of hospitals with limited assistants and absence of sterile salt solution he has used unsterile salt solution by allowing the sigmoid and colon to be slowly filled with the liquid. This is easily accomplished in the Trendelenburg position and the peritoneal cavity opened to permit of the ready guidance of the tube above the pelvic brim. Large quantities can be used in this way without hindrance in the field of operation. The rapidity of the absorption can only be appreciated by actual observation. Another use of the saline solution is shown in the fact that for a number of years he has not flushed a cavity nor used the drain. He has found that the filling of the peritoneal cavity after the tampon has been placed tends toward the dissolution of clots and the carrying off of effete material within the pelvis through the capillarity of the tampon. He has never had a bad result from this method. There are no certain indications for its use, but on the other hand he is certain that many a case of sepsis, septic nephritis and low cardiac vitality has been saved. Several cases are reported.

54. Ectopic Pregnancy.—From his own experience and that of his confrères Clarke is satisfied that no hard and fast rule should be established for the management of all cases of shock or collapse from rupture occurring in ectopic gestation. Shock is no guide to the amount of hemorrhage, even if it is large it may not long continue. In such cases much can be successfully effected by way of stimulation, opiates and employment of salt solution. Constitution and condition of the patient should be considered and perfect quietude should be enjoined. Operation is not always easy and the results are sometimes far from being satisfactory. The object of immediate treatment of whatever character is to lessen suffering and save life if possible. If operation can be dispensed with until more favorable conditions are present, it is the better course to pursue.

56. Rectal Stricture in Women.—Watkins describes a new operation, which consists in taking a portion of the vagina to make up a deficiency in the rectum by separating the recto-vaginal septum along the median line and making it one canal, as would result from complete perineal laceration, following this by suture of the vagina to the rectal mucosa on either side

with fine catgut; then performing a section of the vagina on both sides, making a blunt dissection of the two flaps on either side, with suture of the vaginal flaps thus transporting a part of the lumen of the vagina to the rectum. He says it is not difficult after turning a large amount of the vaginal mucous membrane into the rectum to restore the sphincter ani, as the lower end of the two flaps mentioned are in close proximity to the ends of the sphincter muscle.

57.—See *THE JOURNAL* of August 9, p. 304.

60. **Ovulation.**—The conclusion reached by Drennan is that ovulation occurs in the middle of the intermenstrual period.

63.—See abstract in *THE JOURNAL* of October 4, p. 857.

66.—See abstract in *THE JOURNAL* of October 25, ¶4, p. 1017.

69. **Chronic Enteritis.**—Turck's paper calls particular attention to the disorders of the splanchnic circulation as a cause of this condition; not only the obstructive, or passive form, but congestion without obstruction may become a potent etiologic factor in enteritis, such as congestion due to chilling of the surface, exposure after sweating. He has experimented with various irritants on the intestine with special observation as to the effect in regard to splanchnic congestion, and he finds that the effect of such a congestion is to cause an enormous loss of the normal resistance to infection. He reports a number of cases illustrating his views, showing the association of disturbance of the abdominal circulation with chronic enteritis, and that an important indication in the treatment of this condition is the correction of these disturbances. He reviews the treatment, the use of intestinal cleansing injections, gastric lavage and gastric gymnastics with the rubber stomach bag, and describes a practical method which he considers to be useful in some forms of enteritis such as mucocolitis and in its later stage, membranous colitis, which consists of adding 3 to 5 per cent. of ground slippery elm bark to water, adding any antiseptic or medicaments that may be desired in using it for injections or lavage. It forms a thin mucilage which overcomes all the irritating effects of the water and allows of a higher degree of heat of injection. With these he also uses pneumatic gymnastics, which he has described elsewhere, to affect favorably the circulation.

78.—This article has appeared elsewhere. See *THE JOURNAL* of October 25, ¶36, p. 1072.

87. **Otitis Media.**—Carhart calls attention to the importance of infection by way of the middle ear and the large proportion of children that have suffered this. According to Ponfick's statistics in 100 consecutive autopsies otitis media existed in all but 9, though not suspected in the majority. He thinks the examination of the ear should be a routine practice. The principal thing in treatment is to prevent the retention of infective products in the ear.

91. **X-Rays in Cancer.**—Deming reports a number of cases selected on account of their being advanced types, which were treated by the x-ray. He thinks this agent has the power of relieving pain in the majority of cases. An action in all cancerous tissues is obtained which unquestionably in many instances has, at least, prolonged the lives of hopeless cases, and so far as known produced in many others most flattering results. We have yet to learn how lasting the effect is. While in strictly operative cases we can not for any reason substitute new methods concerning which comparatively little is known, in operable cases where recurrences have followed operations, it is to be without question recommended, as well as employed after operation as a preventive before secondary lesions have occurred. All of his cases were treated with the tube close to the skin for the first few treatments, the length of exposure varying from five to ten minutes, and Mueller's tube was generally used in connection with the coil. Where only a small area required treatment a glass funnel was employed. Following the raying the cases were sprayed with static breeze which acted as a counter-irritant. He finds that frequent exposures with high intensity acted the best at the commencement of treatment, particularly in severe cases, later using some prolonged but less frequent treatment, with penetration somewhat reduced.

96. **Tuberculosis.**—The early symptoms of tuberculosis, such as increase of pulse, slight cough, dyspeptic disorders, nervous irritability, quick fatigue, etc., are reviewed by Pottinger, who calls attention finally to the tuberculin test which he advocates as a valuable diagnostic method, without the dangers that are charged to it. The x-ray and sputum examinations are also mentioned.

102. **Apocynum Cannabinum.**—Hildreth finds this drug very useful in edema accompanying varicose conditions, especially the varicose ulcers of elderly persons, and in this his experience agrees with that of others. He has also found it useful in general anasarca from other causes. How it acts is a question, yet the clinical fact is more valuable than the theory. In a general way it seems to act like digitalis, but has no cumulative tendency and no unpleasant after-effects if given in moderate doses. The preparation he has used most is Lloyd's tincture in doses of 2 to 3 minims in water every three or four hours. If given for some time a tolerance may be established requiring the administration of larger doses. He has never used it in the dropsy accompanying nephritis; it could hardly be expected to act as well as in the more passive conditions. It is said to be of value, however, in chronic Bright's disease, lessening the albumin and casts as well as the anasarca.

110.—This article has appeared elsewhere. See *THE JOURNAL* of October 25, title 53, p. 1069.

113. **Gastric Disorders.**—Harbin calls attention to the disorders of digestion due to enteroptosis and hyperacidity and the methods of their diagnosis and treatment. He says, in conclusion: "1. Every general practitioner can make a diagnosis of gastroptosis by the splashing sounds. By palpation he can recognize a nephroptosis and greatly relieve both conditions by an abdominal belt. 2. One-half of all digestive disturbances are attended with hyperacidity. 3. We can not diagnose hyperacidity with certainty, except by a test breakfast. 4. Lavage in mornings before breakfast with calcined magnesia relieves the pain and discomfort of hyperacidity. 5. The intragastric application of the faradic current gives strength to the involuntary muscles of the digestive tract and the voluntary muscles of the abdominal wall. 6. The physician and gynecologist too often consider gastric symptoms as a reflex disturbance of diseased female generative organs."

118.—This article has appeared elsewhere. See *THE JOURNAL* of October 25, title 53, p. 1069.

119.—*Ibid.*, ¶36, p. 1072.

121. **The Criminal.**—Pinckney's article is a discussion of the degenerate in relation to criminality. He calls attention to the fact that this country and Australia were settled under very different conditions, and that both developed alike, notwithstanding the number of degenerates and criminals transported to Australia inside of 100 years and the law-abiding high-class population that originally settled this country. This fact is in striking contrast to the increase of insanity in all civilized countries. Criminality seems rather to run itself out, while degeneracy still more tends to the disease consequence of insanity. He says it is evident that the innate restraining forces in the criminal are coming to the top.

123. **The Southern Negro.**—Perry reviews the facts in regard to the tendencies of the southern negro under modern conditions, the spread of venereal diseases, which is greater on account of their lack of control, tuberculosis which formerly was almost unknown and is now becoming a scourge, and insanity, which has increased twenty-fold. He does not wish to appear pessimistic, but simply to state facts without prejudice to those honest negroes who are endeavoring to elevate their race. He hopes that with their wider knowledge of facts some good might come to the negro and to society at large.

131. **Prostatic Hypertrophy.**—Prioleau concludes that in the majority of cases this condition is in the scope of the general practitioner's work, and that the majority of even aggravated, infected cases can be relieved and made comfortable without capital surgical intervention, but with judicious, cautious, aseptic catheterization, bladder washings, selected

diet, proper clothing and abstinence from alcohol and carbonated beverages.

132. Tuberculosis.—McIlhaton gives facts to show that tuberculosis is largely dependent on external conditions, referring in support of this view to the conditions among the negroes who in slavery times were almost free from the disease. The coolie experience in Cuba is also adduced as well as a Spanish colony in Central America, which immigrated there on account of its general tuberculous condition. It consisted at first of only ten families, living isolated with constant intermarriage, but has now become a remarkably superior and non-tuberculous community. On the other hand, non-tuberculous families by changing their modes of living have become uniformly tubercular, and he gives an instance. He asks, in conclusion, is tuberculosis a disease of environment only?

FOREIGN.

Titles marked with an asterisk (*) are abstracted below. Clinical lectures and single case reports are omitted unless of exceptional general interest.

British Medical Journal (London), October 25.

- 1 *A Discussion on the Treatment of Inoperable Cancer. Henry Morris and others.
- 2 *The Treatment of Inoperable Cancer of the Breast by the X-Rays. Thomas Bryant and others.
- 3 *A Discussion on Tuberculosis of the Testis, Prostate and Seminal Vesicles. Thomas Myles.
- 4 Two Cases of Chronic Pancreatitis Treated by Laparotomy. Edmund Owen.
- 5 *Experiences in the Extirpation of Tuberculous Lymph Glands During the Last Thirty Years. Rushton Parker.
- 6 *The Value of Imperfectly-Descended Testis. (To be continued.) W. M. Eccles.
- 7 Discussion on Radiography, X-Ray Treatment, the High-Frequency Method and Light Treatment. Dr. Freund and others.
- 8 A Note on the Histology of X-Rayed Lupus Vulgaris. George Pernet.
- 9 *The Pathologic Changes in the Skin Produced by the Rays from a Floues Lamp. J. M. H. MacLeod.
- 10 The T. R. Tuberculin Treatment of Lupus Vulgaris at University College Hospital. H. Radcliffe Crocker and George Pernet.
- 11 Blastomycetic Dermatitis in the Negro. T. Caspar Gilchrist.
- 12 A Discussion on the Treatment of Psoriasis. Malcolm Morris.
- 13 Seborrhea. Norman Walker.
- 14 Tumors of Xeroderma Pigmentosum. George Pernet.
- 15 The Heart and Nervous System. David Ferrier.
- 16 Serumtherapeutics and Carcinoma. Wm. James Hoyten.

The Lancet (London), October 25.

- 17 *The Heart and Nervous System. David Ferrier.
- 18 Tuberculosis of the Peritoneum from a Clinical Point of View. Edmund Owen.
- 19 *Some Morbid Conditions of the Mouth. Edmund W. Roughton.
- 20 Illustrative Cases of Gunshot Wounds of the Skull and Brain. L. G. Irvine.
- 21 *Mental Dissolution the Result of Alcohol. Robert Jones.
- 22 Case of Extrauterine Associated with Intrauterine Fertilization, in Which Abdominal Section was Performed. John Phillips.

Intercolonial Medical Journal of Australasia (Melbourne), September 20.

1. **Treatment of Inoperable Cancer.**—After an elaborate review of the various methods of treatment, including serum-therapy, phototherapy, radiotherapy, etc., Morris offers the following conclusions: "1. That the bacterial treatment of malignant disease is not of the slightest use in carcinoma; that not one-half of the cases of spindle-celled sarcoma disappear under treatment with Coley's fluid; that in cases of carcinoma, other than the spindle-celled, Coley's fluid is not of value; that the treatment by Coley's fluid has many dangers, and should never be employed except in absolutely inoperable cancer. 2. That Beatson's treatment is limited in its action to cases of mammary carcinoma . . . and even in these cases only a small proportion are influenced by the treatment, while neither as a cure nor as a palliative can it be relied on in any given case. 3. That rodent ulcer has in Finsen's light and in the x -rays its most successful treatment . . . and that this is true not only of cases otherwise inoperable, but also of operable cases, because of their excellent cosmetic results, and of their effect on insidious and non-evident foci. . . . 4. That sarcoma, epithelioma and the other forms of carcinoma are best treated, whenever possible, by early excision; and that all forms of treatment hitherto tried in inoperable cancers of these kinds are uncertain and inconstant in their effects, and unreliable as to the durability of the results they produce. In the vast majority of cases they are quite without palliative influence of any kind, except possibly in relieving pain. 5. That the boundary line between what are considered operable and inoperable cases needs revision from time to time; that the tendency to extend the limits of operable cases needs in some instances to be restricted, and in others there may prove room for further extension. 6. That it is open to question whether some of the operations performed for relief . . . should not be abandoned, and whether in other cases palliative operations ought not to be more often performed. 7. That investigations into both the cause and nature of the cancer are of the first importance, as being more likely to ultimately lead to cure than any treatment at present known. 8. That, with few exceptions, the attempts to cure cancer by means other than early and free operations have been hitherto almost invariably futile. Our complete ignorance as to the cause, nature, and curative treatment of cancer has long pointed to the necessity of instituting a comprehensive, collaborative and coöperating inquiry into the whole question of malignant disease; and it is a source of great satisfaction to know that at last, though after many vicissitudes, sufficient funds have been raised to enable the two Royal Colleges to make, at any rate, a beginning in this wide-reaching and unspeakably important subject."

2. **X-Rays in Cancer.**—The discussion on this subject is opened by Bryant, who reports cases and remarks that much good can be secured in inoperable cancer of the breast and skin; and there is reason to believe, in cancerous disease of the rectum, that relief of pain and the arrest of the progress, if not the disappearance, of local disease, can be obtained by the x -rays, but that at present surgeons are not justified in leading patients to expect a cure. It is essential that the treatment should be in the hands of medical experts and not allowed to pass into those of mere mechanics. In the discussion following several surgeons reported good results from the use of the x -ray and others reported their failures.

3. **Tuberculosis of the Testicle, Prostate and Seminal Vesicles.**—This subject is treated with conservatism by Myles, who concludes that where only one or two small nodules of chronic type appear in a man of good physique without any signs of general infection and without any enlargement of the prostate or vesicles, a partial operation would generally be sufficient and a more radical operation could follow it if necessary. In those cases where the prostate and vesicles are also involved he does not put much reliance on operative treatment and where suppuration already exists and the testicle is markedly enlarged and practically useless he advocates total extirpation without delay. Where both are involved he would almost shrink from advising complete castration, but it might be a graver responsibility not to advise it. Where general infection exists, of course there is no question that operation is inadvisable. Neither does he believe that a very hopeful outlook in operative treatment of tuberculosis of the bladder can be expected and as regards tuberculosis of the vesicles and limited to this organ, he can say nothing, as he has had no experience of this sort.

5. **Tuberculous Lymph Glands.**—Parker argues the following two points: 1. A more frequent and thorough submission to operation of the milder cases of tuberculosis of the glands; 2, a bolder and more frequent attack of advanced and extensive cases while they continue to occur. He warns everyone not to expect too much from scraping and scooping, but more thorough extirpation is required.

6. **Cryptorchidism.**—The value of an imperfectly descended testis is discussed by Eccles, who reviews the arguments for and against its removal. He thinks that where there is unilateral arrest of one accompanying hernia of the same side, a radical operation is indicated. The testis should be placed in the scrotum if it can be done easily and with the probability that it will not recede, but under other circumstances it should be preferably returned in the abdomen unless there are special reasons for thinking it is more advisable to remove it. If both are alike arrested it is injudicious to cut away either of them, for the amount of internal secretion that they together may produce may be sufficient to cause the proper development of the body in general, while that of one alone may be insufficient.

9. **Pathologic Changes in the Skin from the Finsen Light.**—MacLeod has studied the histologic changes produced by actinic rays in lupus vulgaris in two cases and gives here the details. He says in conclusion it may be asserted: "1. That the action of the actinic rays from an arc lamp on the granuloma of lupus is essentially destructive, and that this destructive process is indirectly produced and is simply the result of an ordinary inflammatory reaction. 2. That the effect of the rays on the surrounding healthy tissue is negligible, so that the doubtful tissue in the neighborhood of a patch of lupus may be safely exposed to them without subsequent injury and scarring. 3. That the destructive process, if the rays are judiciously employed, is not of such an intensity as to prevent subsequent repair, and a few days after it has reached its acme a process of construction sets in similar to that which takes place in the healing of inflammation. 4. That the process of construction is capable of replacing the destroyed granuloma with healthy fibrous tissue, forming a pliable scar, and the epidermis completely recovers from the edema caused by the action of the rays. Hence from the histologic standpoint the treatment of lupus and other granulomatous affections of the skin by the actinic rays is an ideal one."

17. See also title 15 above.

19. **Morbid Conditions of the Mouth.**—This third lecture by Roughton discusses the question of alveolar abscess. This even may be fatal, and he has met three such cases, one of pyemia starting from abscess, another of invasion of the cranial cavity and contents and the third of perforation of the common carotid artery without evidence of pyemia. The last case is notable on account of the absence of pain, the slight degree of fever, with almost entire absence of suppuration and the purely local nature of the process generally. A rapid

ulcerative process laying open the carotid artery was the cause of death. He thinks the peccant organism in the case was the *Streptococcus pyogenes*. Treatment should be energetic, the cause should be removed, but this does not always mean the sacrifice of the tooth, which he thinks is made a little too often. Chronic fistulous and blind abscesses are frequent, but the latter is seldom recognized until the tooth is removed. The treatment of the fistulous form consists in removing the septic material from the pulp chamber of the tooth, and if the tooth can not be rendered useful after this, it should be extracted. He closes the lecture with remarks on dental caries and teaching children the habit of cleansing the teeth. It can not be practiced too early, and in fevers and other diseases the teeth should be cleansed by the nurse. He asks the general surgeon whether he is in the habit of sterilizing the mouth before operating on the jaws or tongue. He does not find the importance of the subject duly insisted on in text-books. The cleansing should be begun many days before operation, if possible.

21. **Alcoholism.**—Jones' paper gives interesting statistics on the consumption of alcohol and its toxic action on the individual and the race. He finds that while the English people drink less per head than those of continental nations, yet the cost of alcoholic liquors in that country last year amounted to nearly \$20 per head, not including beer, of which 30 gallons per head were consumed. Moreover, a still more striking fact is that the death-rate from alcohol drinking during the last fifteen years has increased about 42 per cent. in men and 100 per cent. in women. In some of the larger towns it is greater than that from scarlet fever, and all other zymotic diseases taken together. The statistics of alcohol and insanity are reviewed, and he finds from the lunacy commission reports that the cases for which alcohol is assigned as the cause averaged 21.8 per cent. of the whole number for males and 9.5 per cent. in females in England, with a still higher proportion in Scotland. England is over-supplied with saloons. The special effects of alcohol are noticed, and he gives some interesting psychologic data as showing the effects on the mental condition, from investigations made in the laboratory of the Claybury Asylum under the direction of Dr. F. W. Mott. The pathology of chronic alcoholism is also described from data obtained from the same source. Jones believes in the control exercised on the sale of drink by restrictive legislation, and he says he does not think, but knows, that we can make not only our men and women, but villages and even larger communities sober by Act of Parliament if it is enforced. Therefore, he thinks the best working hypothesis for the prevention and cure of all forms of alcoholic disorders, whether mental or physical, must be based on the practice of total abstinence.

23. **Fibrinous Bronchitis.**—The condition discussed by Harris is considered by him to be due to congestive or low inflammatory edematous exudates from the serous lining of the respiratory processes and the cause of this in most cases is engorgement of the pulmonary circulation by temporary or permanent incompetence of the left ventricle, with competence of the right ventricle, but that the local congestion may, in some instances, be produced by strong vasomotor influences when disease already exists in the tubes; and that the former condition is responsible for the exudation occurring from the lungs instead of the strain being referred back to the general venous system. That fibrinous casts have been found in typhoid, variola, etc., is not an argument against the above conclusions, because we have in all these high temperature and the action of toxins, which tend to weaken the heart and produce edematous fluids in the lungs. In phthisis a local mechanical obstruction may produce local edematous exudates.

24. **Tuberculosis.**—Turner protests against the routine administration of guaiacol and creosote in this disease, which he thinks has become alarmingly common and reports cases. These drugs are apt to impair the digestion, and if we take care of the stomach the lungs will be better able to take care of themselves.

25. **Tuberculosis of Miners.**—The frequency of tuberculosis among miners is noted by Cowen, who finds that there

are six times as many deaths among them from consumption as from fatal mining accidents, and that the death-rate among miners over 45 is at the rate of 13 to 1 as compared with that of women of the same class. He thinks we should insist on the destruction of sputum in the mines and elsewhere and the proper ventilation of mines and bedrooms, as well as the other well-known prophylactic measures against this scourge.

33. **Traction of Tongue for Asphyxia from Gases.**—THE JOURNAL has frequently referred to Laborde's method of resuscitation of drowned persons by rhythmic traction of the tongue. He now announces that it is a life-saving measure also in cases of asphyxia from inhalation of carbon oxid, sewer gas, chloroform and illuminating gas. In one case a child had been resuscitated by this means after apparent death from drowning, with no signs of pulse or respiration forty-five minutes after he had been taken from the water. The teeth were pried open and rhythmic traction exerted on the tongue while the throat was tickled. In five minutes the child vomited and respiration was re-established at the same time. Ten days later the parents sent for the doctor again, as the child had suddenly died without any sign of sickness. He was in cadaveric pallor, the limbs relaxed, no sign of heart action or respiration. The air of the room was laden with the products of defective fuel combustion. After energetic traction of the tongue for ten minutes the child was restored. A second case was a woman who had tried to commit suicide by inhaling charcoal fumes. All measures to resuscitate her proved futile until five minutes of traction of the tongue restored the respiratory function. In a similar case the patient continued to breathe faintly on removal to the open air, but profound coma persisted, with complete loss of general and corneal sensibility, the entire body cyanosed, respiration jerky and pulse irregular and almost imperceptible. Inhalation of oxygen, artificial respiration, etc., failed to alter this condition, but traction of the tongue aroused the patient for an instant, after which she relapsed again into the coma. By the end of a half hour of this exercise with the tongue the corneal sensibility was faintly perceptible in one eye, and by the end of another half hour the pulse and respiration seemed a little less irregular and the other cornea exhibited a slight reaction, but the patient sank again into profound coma whenever the tractions were suspended. After two hours more oxygen was administered, on which the condition at once became alarming, with arrest of pulse and respiration, but again the patient was revived by the tractions. They were renewed again several times during the day and the coma gradually wore off by the end of three days. The engineer and fireman in a torpedo boat became asphyxiated and fell wedged behind the boiler in such a way that no means of resuscitation except traction of the tongue were possible, and this only for one of the men. It was promptly applied and he was restored so that he could extricate himself. The other could not be reached until this occurred, and it was then too late. In a case of intoxication from illuminating gas the patient was restored after forty-five minutes of traction of the tongue. In another case thirty minutes sufficed, but the tractions had to be repeated several times during the day as the respiratory function seemed again to flicker and be on the point of going out. [The recent death of the novelist Zola from carbon oxid, generated by a stove using "patent fuel" with the chimney accidentally obstructed, renders this subject peculiarly timely. He had fallen on the floor and had been dead for hours when found, while his wife still in bed, although respiration and pulse had vanished, showed a certain pinkness of the skin, and after twenty to twenty-five minutes of rhythmic tractions of the tongue, supplemented by Sylvester's method of artificial respiration, she was restored. (See editorial in last issue.) The *Gaz. Med. de Paris* states that an hour elapsed after the asphyxiated pair were discovered before a physician could be found to attend them. The lack of provisions for emergency relief at Paris is a theme to which it frequently recurs, constantly holding up as a model to the Paris authorities the police patrol wagons and stations in certain American cities.—Eo.]

34. See THE JOURNAL, November 1, p. 1123.

35. Esthetic Ablation of Innocent Tumors of the Breast.—Mórestin describes two cases in which he removed a tumor about the size of a walnut from a prominent location on the breast of society women, without leaving a trace of the intervention nearer than the axilla. He made a large incision in the axilla and opened up a passage down to the tumor under the skin. He was then able to work the part of the breast containing the tumor up into the incision and excise it with ease at this point. When the breast was released it slid back into its normal position and there is no trace of the operation except the hidden scar in the axilla.

36. Technic of the Prerectal Incision.—Proust illustrates with 11 large cuts the various steps of the technic by which it is possible to open up a wide avenue of entrance into the small pelvis through the perineum without injury of any organ. He calls special attention to the detachable zone which he has discovered back of the prostate. The urethro-rectal muscle is the key to this zone and must be severed before it can be entered.

38. Inoculated Metastases of Carcinoma.—Olshausen states that he performed a laparotomy on account of what he found to be an inoperable carcinoma of the ovaries, and closed the abdomen at once. The patient died two weeks later from embolism and the autopsy disclosed hundreds of metastases in the peritoneum which had not been there at the laparotomy, fourteen days before. In another case the patient had had both ovaries removed on account of papillary cystomata in the broad ligament. She was 29 years old and has never menstruated since. Twenty years later a large tumor developed in the abdominal wall projecting outward instead of inward, and bounded on one side by the linear scar left from the preceding laparotomy. It spread along one side of the scar, but did not invade the other side, demonstrating, he thinks, its character of a metastasis from inoculation. He has witnessed a number of cases of pseudomyxoma developing in the peritoneum after ablation of an ovarian cystoma with jelly-like contents. Marchand observed these pseudomyxomata on the upper surface of the diaphragm in one case, corresponding in every respect to the primary tumor. Baumgarten has also published a case in which metastasis of a benign tumor had occurred in the abdominal wall. After extirpation of a non-malignant ovarian cystoma a number of small metastatic tumors developed, both in and outside of the peritoneum, provided with the same epithelium noted in the primary tumor.

39. Agglutination of Streptococci.—Meyer has established that streptococci derived from various sources may be agglutinated by corresponding prepared serums. Also that there can be no question as to the diversity of various families of streptococci. His research has also convinced him that it is unwise to use bacteria for the production of a bactericidal serum for therapeutic use, which have been rendered more virulent by passages through animals. The specific agglutination is disturbed by this process, which he thinks is an argument against it.

41. Painful Feet.—Schanz describes the class of patients who complain of pains in the heel, sole, joints or toes, even of obstinate corns, but examination of the foot reveals nothing abnormal. Such cases are all attributable to flatfoot. The instep may appear normal, when in reality an unusually high instep has been transformed into a very low one and thus be really flatfoot, although it is still within the limits of the normal instep. There is no typical localization of the pains of flatfoot. Whenever he meets a well-dressed man who clings to old, worn-out shoes as the only ones he can wear with comfort, he is seldom wrong in the diagnosis of flatfoot. Treatment should be that for flatfoot, and he has found a celluloid rounding sole a convenient appliance. It can be molded to the foot when soft and the shape changed at will.

46. Tavel's Salt-Soda Solution.—See THE JOURNAL of November 8, p. 1219.

51. Pathogenesis and Successful Treatment of Angina Pectoris.—Breuer confirms the remarkable benefit to be derived from theobromin in these conditions as announced by Askanazy in 1895. The diuretic influence of this drug is

familiar, but its property of promptly arresting the pains of angina pectoris, cardiac asthma and allied conditions is less generally known, and yet Breuer considers it one of the most blessed facts in modern therapeutics. He describes over a dozen cases in detail, showing its rapidly beneficial influence in all pains of arterial origin. They form a series ranging from pure angina pectoris to attacks of pain attributed by the patients to the head, stomach, shoulder, kidney or intestines, and apparently with no features in common with angina pectoris, yet all show by the prompt response to theobromin that they have a common origin in the arteries and that theobromin has a specific action on the latter. Arteriosclerosis and certain other affections of the arteries are liable to cause constant pains in the vessels which may radiate to remote regions. The pains may be due to increased blood pressure and distention, but they are also liable to be caused by spasmodic contraction of the arteries. These contractions occur by preference in the smaller arteries and are the result of pathologic or pathologically exaggerated reflexes originating in the diseased vascular wall. They are set in motion by various causes which raise the blood pressure, emotions; muscular exertion, the horizontal position in sleeping, etc. They are especially liable to occur in the organs which require the largest supply of arterial blood, such as the digestive tract, heart and muscle. The arterial fluxion induced by increased function starts the attack of pain. The spasmodic contraction of the arteries causes symptoms of ischemia as the arterial supply is cut off from muscular organs. In the extremities it becomes evident as intermittent claudication; in the digestive tract as paresis or meteorism; in the heart, as sudden inadequacy and paralysis. Sensory phenomena may be superadded to these and it becomes difficult to decide whether the pains are due to the vascular spasm or to the ischemic parenchyma. When the vessels of the heart are directly or indirectly involved the specific angina cordis develops. The lesions of the heart arteries may radiate the pain to remote regions. The spasm of the heart arteries is peculiarly intense when it is not the result of the usual causes, but is due to direct irritation of the intima by a thrombus or embolus. This explains the sudden death that may occur from a small embolus in one of the terminal ramifications of a coronary as well as in case of obstruction of a large artery from this cause. Theobromin has evidently some action on the spasmodic contraction of the arteries, and when this is controlled the pain ceases. It may also act by diminishing the reflex excitability or by reducing the arterial pressure. Be this as it may, the fact is established that theobromin is a powerful and harmless remedy for pains on an arterial basis. Breuer always gave it in the form of diuretin (Knoll), in doses of .1 gm. four or five times a day, and in the severest cases 3 to 4 gm. a day. The only objection to its use, he remarks, is the high price charged for the preparations of theobromin.

52. Anatomy and Pathology of the Biliary Organs and Pancreas.—Büngner's communication was read at the Naturforscher Congress and presented some new views. He found in 58 cadavers that the common bile duct passed directly through the head of the pancreas in 95 per cent. and was so solidly imbedded for a distance of about 2 cm. that it could not be detached from the head without cutting. In 98 to 99 per cent. of all cases the bile duct and the pancreatic duct did not unite, but terminated at separate points in the duodenum. The mouths of the two ducts were separated by a space of .2 cm. on an average, and generally the pancreatic duct passed beneath the bile duct. The pancreatic duct had a small branch in 10 per cent., this branch debouching separately in the duodenum. These facts explain why the symptoms of obstruction of the biliary passages are liable to accompany any affection of the head of the pancreas. An isolated affection of the biliary system, on the contrary, is not accompanied by retention of pancreatic juice. The latter is unaffected by a lesion in the bile duct, while the flow of bile is not affected by a lesion in the pancreatic duct. But a lesion in the ampulla where both ducts debouch into the duodenum is liable to cause obstruction of both ducts and the symptoms of biliary retention are added to those of pancreatic retention.

73. **Circular Incision for Leg Ulcers.**—Mancini urges the importance of stretching the nerves during this operation, and also to make the incision higher on one side than the other, to add to its length. This method of treating varicose ulcers has proved remarkably successful in his extensive experience. [See THE JOURNAL of August 2, p. 289.]

75. **Treatment of Chronic Meningo-Myelitis.**—Personali has treated 16 cases of chronic meningo-myelitis by suspension and immobilization. Eight have been clinically cured, 4 extremely improved, 2 refused to continue the course and the results were negative in only 2. He excludes cases of syphilitic origin and also all very old, inveterate ones. He commences treatment with suspension for one minute a day, increasing by one minute to the fourth day, then applying four minutes' suspension a day for ten or twelve days. He then immobilizes the patient in a plaster corset in the dorsal decubitus. By the end of the third month the patient is allowed to sit up in bed, commencing very gradually, and finally to walk a few steps. He then suspends the patient as before and applies a second cast, but without such strict immobilization in bed. This cast is removed in two months and a strong corset applied and worn for two or three months, when the cure is complete. The effect of this treatment has been marvelous in his experience. The pains disappear in a day or so and the patient gains rapidly in weight. Constipation should be guarded against, and he supplements this mechanical treatment by daily injection of arsenic, for which he prefers a mixture of 2.5 gm. sodium cacodylate and 5 drops phenicated alcohol in 50 gm. distilled water.

76. **Anastomosis of Severed Vas Deferens.**—Ferraro has experimented on dogs for a method of uniting the stumps after the vas deferens has been intentionally or accidentally divided. He makes an incision across half the vas a few mm. from the end of the stump, and then incises from the middle of the first incision to the end of the stump, forming a T. The end of the vas released by these incisions spreads out into a square, almost flat, flap. The same procedure is repeated on the opposite side of the other stump, and the two square flaps thus produced are sutured together. The anastomosis is perfect and solid.

78. **Indirect Secondary Atrophy of the Nervous System.**—This elaborate research by Tanzi details experiments made on rabbits, dogs, etc., as to the effects of destruction of the sensory trunks traced back through the other neuron elements to the cortex. They find that the lesions in the nervous system of new-born animals do not cause the complete degeneration of the secondary neurons that is produced in the neuron directly wounded. The neurons having a simple connective relation with those wounded, but not directly injured themselves, may undergo processes of atrophy but not of total destruction. In consequence of the destruction of the primary optic neurons, the secondary tracts undergo a process of atrophy that does not alter the morphologic character of the elements. They become diminished in size, but preserve in a lesser degree their external configuration and their internal structure. In the nuclei where the primary tracts terminate, the atrophy is considerable in mass and is chiefly due to destruction of the nervous terminations of the neurons primarily injured; an interstitial atrophy to which the neurons of the second order contribute in so far as they become lacking in dendritic prolongations and therefore reduce the amount of gray tissue. Indirect atrophy of the neurons of the third and fourth order may be altogether lacking, as, for example, in the visual cortex of rabbits, after enucleation of the eyes. The atrophy continues of the same type, that is, reduction in the size of the cellular elements, but preserving the morphologic character. Tanzi finds that the lower the order of animals the less the atrophy. For instance, there is an absence of cortical atrophy in rabbits; it is only slight in cats, evident in dogs, and in man is also pathologically observed, hence it follows that the cortex is more sensible to the suppression of stimuli in the higher orders of animals. He also finds the same conditions in the organs and cells. The subcortical ganglia which have the most stable and automatic function show much less effect of

the absence of stimuli, while the cortex is most affected. His conclusion is that the most highly developed nervous centers are the most sensitive to suppression of stimuli, and that animals are most affected which have organs highest developed as compared with other animals.

79. **Paresis.**—Lambranzi has observed a case of paresis which commenced by polymyoclonic symptoms, subsequently developing into a well-marked case of paresis.

81. **The Effect of Iodoform on the Nerves.**—Giani and Ligorio have studied the effects of iodoform poisoning on the nerves. They find in the chronic type the lesions are less evident and a large number of the nervous elements escape, while in acute iodoform poisoning, on the other hand, the nervous lesions are always more grave throughout the whole cerebrospinal axis.

86. **Influence of Tracheo-Bronchial Adenopathy in Whooping Cough.**—The almost inevitable inflammation of the tracheo-bronchial glands in whooping cough is evidently a localization of the specific infection, aggravated possibly by secondary infection. It does not cause fever unless so extensive as to constitute an actual complication. When tuberculosis of the lungs follows whooping cough Centeno attributes it in the majority of instances to primary tuberculous infection of these glands.

89. **"Typhic Remedy" in Typhoid Fever.**—Mendez published four years ago the results of successful research on the vaccine of anthrax, and he has since been applying the same methods to the treatment of typhoid fever. He prepares the specific substance in the form of a powder instead of a serum, and reports 65 typhoid patients treated with it with one death. Benefit was apparent in every case. The temperature gradually subsided to normal and the diazo-reaction and albumin vanished from the urine. The general condition became remarkably improved by the third day after the injection and convalescence was established by the fifth to seventh day. He notes as an interesting fact that the roseolæ persist and may not appear until after the temperature and pulse are normal once more. One patient died from perforation of the intestines five days after entering the hospital; in this single case the diazo had persisted unmodified by the injection. No other treatment was instituted in any case except a few injections of caffeine. The author is professor agrégé of clinical medicine and has charge of the antitoxin laboratory.

91. **Topography of Medulla and Cord.**—Valle's article is illustrated with 9 engravings and 11 curves and establishes that the relations between the vertebrae, roots and spinal segments are not so diagrammatic as hitherto supposed. These relations vary somewhat at different portions of the spine, as he portrays in detail.

94. **Relations Between Diphtheria and Angina Phlegmonosa.**—Ernberg describes four cases of diphtheria which developed with the aspect of angina phlegmonosa. As the patients were adults the possibility of diphtheria was not borne so prominently in mind as if they had been children. In differentiating such cases the lack of severe general symptoms at first—in comparison with the intensity of the throat process—speaks in favor of diphtheria, also the pronounced swelling of the soft palate and the characteristic fetor ex ore. The local findings and symptoms seem to be identical in each disease, but in his experience these cases of diphtheria which simulated an angina phlegmonosa proved to be all exceptionally malignant in their course. Energetic antitoxin treatment is indicated, therefore, whenever there is the least suspicion in regard to the true nature of an angina phlegmonosa.

95 and 101. **Catatonia.**—Svenson reproduces the photographs of eleven cases of catatonia and reviews the differentiating points. He noticed in all of them a peculiar limitation of the field of mental conceptions and a remarkable tenacity in the dominant conception, except in the cases of stupor. Eight of the patients were women, only one married. Three were men, two were married. He refers to the relations between familial myoclonia and catatonia, and Lundborg completes the

data in this line, as he has had occasion to see two cases in which myoclonia was associated with catatonia. Faber of Copenhagen described last year two cases in sisters; one was a typical myoclonia and the other had commenced as catatonia at the age of 17, and after the patient had been some time in the hospital the symptoms of familial myoclonia developed. He has collected in the literature 37 cases of familial myoclonia, but in 10 the patients had not reached the age of puberty, when catatonia is most liable. Omitting these cases, 3 of the remaining 20 exhibited many points in common with catatonia. Some of the cases are imperfectly reported, and it is possible that the two affections were associated in more than the 3 mentioned.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

GENITO-URINARY AND VENEREAL DISEASES. A Manual for Students and Practitioners. By Louis B. Schmidt, M.Sc., M.D., Associate Professor of Genito-Urinary Diseases, Chicago Polyclinic. Series Edited by V. C. Pedersen, A.M., M.D., Recently Assistant Demonstrator of Anatomy, College of Physicians and Surgeons. Illustrated with 21 Engravings. Cloth. Pp. 249. Price, \$1.00. Philadelphia and New York: Lea Brothers & Co.

AN INTRODUCTION TO DERMATOLOGY. By Norman Walker, M.D., Fellow of the Royal College of Physicians of Edinburgh. With 43 Full-Page Plates and 47 Illustrations in the Text. Second Edition, Revised and Enlarged. Cloth. Pp. 301. Price, \$3.00. New York: Wm. Wood & Co. 1902.

TRANSACTIONS OF THE STATE MEDICAL ASSOCIATION OF TEXAS. Thirty-fourth Annual Session, Held at Dallas, Texas, May 6, 7, 8 and 9, 1902. Cloth. Pp. 587. Austin, Texas: Von Boeckmann, Schutze & Co. 1902.

TRANSACTIONS OF THE COLORADO STATE MEDICAL SOCIETY. Thirty-second Annual Convention. By-laws and List of Members. Cloth. Pp. 452. Denver: Published for the Society. 1902.

THE PUBLIC AND THE DOCTOR. By a Regular Physician. Cloth. Pp. 149. Price, \$0.50. Dallas, Texas: Published by Dr. B. E. Hadra.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., from October 25 to 31, inclusive:

Corbusier, Harold D., contract surgeon, U. S. A., is relieved from further duty in the Division of the Philippines, and upon the expiration of his present leave of absence will report in person to the commanding officer, Ft. Columbus, N. Y., for temporary duty, and by letter to the commanding general, Department of the East.

Davis, Wm. B., major and surgeon, U. S. A., is granted leave of absence for three months, to take effect on his being relieved from duty at Ft. Myer, Va.

Juenemann, Geo. F., contract surgeon, U. S. A., is granted leave of absence for one month.

Kemp, James F., contract surgeon, U. S. A., is granted leave of absence for one month.

McCallom, Francis M., asst.-surgeon, U. S. V., is honorably discharged from the service of the United States, to take effect Nov. 5, 1902, his services being no longer required.

Rhoads, Thomas L., first lieutenant and asst.-surgeon, U. S. A., the leave granted in Special Orders No. 203, Sept. 11, 1902, Department of California, is extended one month.

Southall, Edward A., capt. and asst.-surgeon, U. S. V., is honorably discharged from the service of the United States, to take effect Nov. 6, 1902, his services being no longer required. He will proceed to his home.

By direction of the Secretary of War the following-named assistant-surgeons, U. S. A., recently appointed, now at the places indicated after their respective names, will report in person at 9 o'clock a. m., Nov. 6, 1902, at the Army Medical Museum, in this city, to Col. Calvin DeWitt, assistant surgeon-general, U. S. A., president of the faculty of the Army Medical School, for the course of instruction prescribed in Paragraphs 542 and 543, Army Regulations, 1901:

First Lieut. Louis C. Duncan, Meriden, Kan.
First Lieut. Edward M. Talbott, Falls Church, Va.
First Lieut. John A. Clark, Washington, D. C.
First Lieut. Samuel J. Morris, Washington, D. C.
First Lieut. Noel I. Barron, Washington, D. C.
First Lieut. J. Morgan Coffin, Phoenixville, Pa.
First Lieut. John W. Hanner, Franklin, Tenn.
First Lieut. Levi M. Hathaway, Owensboro, Ky.
First Lieut. Alexander Murray, Alexandria, Va.
First Lieut. Phillip W. Huntington, Washington, D. C.
First Lieut. James Carroll, Washington, D. C.
First Lieut. James D. Fife, Charlottesville, Va.
First Lieut. William A. Powell, Cairo, Ga.
First Lieut. Leon T. de Wald, New York City.
First Lieut. Jesse R. Harris, Kenmore, N. Y.
First Lieut. George H. Scott, Butler, Pa.
First Lieut. Edwin D. Kilbourne, Chicago.
First Lieut. Robert L. Carswell, Chattanooga, Tenn.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy, week ending Nov. 1, 1902:

P. A. Surgeon W. B. Grove, detached from the *San Francisco* and ordered to the *Prairie*, for duty with the marine battalion aboard that vessel.

Asst.-Surgeon A. Stuart, ordered to duty at the naval hospital, Navy Yard, New York.

Asst.-Surgeon S. S. Rodman, detached from the *Alert*, and, when discharged from treatment at the naval hospital, Mare Island, Cal., ordered home and granted sick leave for two months.

Pharmacist F. T. Gordon, detached from the *Wabash* and ordered to the naval hospital, Boston, for treatment.

Surgeon H. E. Ames, ordered to the *Texas*.

P. A. Surgeon J. E. Page, detached from recruiting duty and ordered to the *Newark*.

Asst.-Surgeon A. W. Balch, detached from the *Monongahela* and ordered to the *Machias*.

Asst.-Surgeon C. H. De Lancy, detached from the *Buffalo* and ordered to recruiting duty with Ensign D. C. Hanrahan, at Knoxville, Tenn.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Oct. 30, 1902:

Assistant Surgeon-General H. D. Geddings, detailed to represent the service at the meeting of the Association of State and Provincial Health Officers at New Haven, Conn., October 28-29.

Surgeon W. P. McIntosh, granted leave of absence for 15 days from November 1.

Asst.-Surgeon J. F. Anderson, detailed as assistant director of the Hygienic Laboratory.

Asst.-Surgeon V. G. Helser, to proceed to Washington, D. C., for duty.

Asst.-Surgeon Carl Ramus, granted 15 days' extension of leave of absence from October 25.

Asst.-Surgeon A. J. McLaughlin, relieved from duty in the Hygienic Laboratory and directed to proceed to New York City (Stapleton) and report to medical officer in command for duty and assignment to quarters.

A. A. Surgeon E. Alexander, granted leave of absence for 5 days from November 1.

A. A. Surgeon C. B. Ford, granted leave of absence for 15 days from Oct. 18, 1902, on account of sickness.

A. A. Surgeon E. T. Hargrave, granted leave of absence for 30 days from October 12.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Nov. 1, 1902:

SMALLPOX—UNITED STATES.

California: San Francisco, Oct. 12-19, 3 cases.
Illinois: Chicago, Oct. 18-25, 7 cases.
Indiana: South Bend, Oct. 18-25, 1 case.
Maine: Biddeford, Oct. 18-25, 2 cases.
Massachusetts: Oct. 18-25, Cambridge, 2 cases; Malden, 1 case; Marlboro, 1 case.
New Hampshire: Oct. 18-25, Manchester, 1 case; Nashua, 18 cases.
New York: New York, Oct. 18-25, 3 cases.
Ohio: Cincinnati, Oct. 18-24, 4 cases; Cleveland, Oct. 18-25, 24 cases, 7 deaths; Youngstown, Oct. 18-25, 4 cases.
Pennsylvania: Oct. 18-25, Erie, 7 cases; Johnstown, 6 cases; McKeesport, 7 cases; Pittsburg, 43 cases, 4 deaths.
Utah: Salt Lake City, Oct. 18-25, 6 cases.
Wisconsin: Milwaukee, Oct. 18-25, 22 cases.

SMALLPOX—FOREIGN.

Barbados: Sept. 28-Oct. 13, 290 cases, 11 deaths.
Canada: Quebec, Oct. 11-18, 2 cases.
Ecuador: Guayaquil, Oct. 4-11, 4 deaths.
France: Rheims, Oct. 5-12, 1 case.
Gibraltar: Oct. 5-12, 1 case.
Great Britain: Bristol, Oct. 4-11, 1 case; Edinburgh, Sept. 27-Oct. 4, 2 cases; Liverpool, Oct. 4-11, 5 cases, 1 death; London, Oct. 4-11, 2 cases; Manchester, Sept. 27-Oct. 4, 1 case.
India: Bombay, Sept. 23-30, 1 death; Madras, Sept. 13-19, 1 death.
Italy: Naples, Oct. 6-13, 4 cases; Palermo, Sept. 27-Oct. 11, 9 cases, 3 deaths.
Russia: Moscow, Sept. 27-Oct. 4, 1 case, 1 death; St. Petersburg, Sept. 27-Oct. 4, 5 cases, 3 deaths.

YELLOW FEVER.

Colombia: Panama, Oct. 13-20, 7 cases, 1 death.
Costa Rica: Port Limon, Oct. 16-23, 1 case.
Ecuador: Guayaquil, Oct. 4-11, 2 deaths.
Mexico: Mexico, Oct. 12-19, 1 death; Tuxpam, Oct. 14-21, 1 death; Vera Cruz, Oct. 18-25, 10 cases, 3 deaths.

CHOLERA.

China: New Chwang, Aug. 31-Sept. 13, 68 cases, 64 deaths.
Egypt: Oct. 12-18, 705 cases, 636 deaths; Alexandria, Sept. 27-Oct. 4, 129 cases, 120 deaths.
India: Bombay, Sept. 23-30, 1 death; Calcutta, Sept. 20-27, 11 deaths; Madras, Sept. 13-19, 1 death.

PLAGUE—UNITED STATES.

California: San Francisco, Oct. 11, 1 case, 1 death; Oct. 16, 1 case, 1 death.

PLAGUE—INSULAR.

Hawaii: Honolulu, Oct. 16, 1 death.

PLAGUE—FOREIGN.

India: Bombay, Sept. 23-30, 76 deaths; Calcutta, Sept. 20-27, 15 deaths; Karachi, Sept. 21-28, 21 cases, 18 deaths.

The Journal of the American Medical Association

Published under the Auspices of the Board of Trustees.

VOL. XXXIX.

CHICAGO, ILLINOIS, NOVEMBER, 22, 1902.

No. 21.

Address.

CONCERNING SOME VACCINAL ERUPTIONS.

CHAIRMAN'S ADDRESS, DELIVERED BEFORE THE SECTION ON CUTANEOUS MEDICINE AND SURGERY, AT THE FIFTY-THIRD ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION, AT SARATOGA SPRINGS, N. Y., JUNE 10-13, 1902.

HENRY W. STELWAGON, M.D.
PHILADELPHIA.

The privilege of presiding over the deliberations of so active a Section as that of Cutaneous Medicine and Surgery is one that I deeply appreciate, and I thank the members for this honor and evidence of their confidence. It is a department of medicine which has in the last twenty-five years made a phenomenally progressive growth in this country, passing from that of scant mention in the rosters of instruction in our colleges to that of a fair share in the regular curriculum, and with rare exceptions to the standing of an examination branch. This is owing to such bodies as this and similar organizations, as well as to the activity of individual workers. While the diseases which it includes are of relatively small gravity and fatality, yet they constitute a class which give rise to considerable physical discomfort, mental depression, personal and often repulsive disfigurement, and in a large number of cases to loss of occupation or incapacity to earn a livelihood. Moreover, the branch includes some diseases which are actively contagious, and others moderately so, and for this reason alone is entitled to full consideration in the training of medical men.

From the standpoint of the public welfare the state should not admit applicants into the field of general practice unless sufficiently competent to recognize and treat contagious and infectious maladies, not only of this, but of all other departments of medicine. State examiners have not yet sufficiently taken this point into consideration, and it should be our duty to urge this and for the public to insist that in the tests of qualifications that contagious diseases should be given a conspicuous place. Moreover, as regards the diseases of our own branch, it is only necessary to mention the various centers of contagion, such as children's asylums, children's schools, day nurseries, barber shops, the common bath and toilet room, laundries, steerage quarters on steamships, etc., as to suggest also the propriety of sanitary inspection of such places.

It is not my purpose, however, to dwell on such aspects of our branch. Nor is it my intention to follow strictly the general custom of the chairman and give a brief review of dermatologic literature and advances of the past year. I had already prepared some data for

remarks in this direction, more especially on the two subjects which the past year or two have brought prominently into the foreground—the value of the various plans of light treatment and the new field opened up by the contributions on blastomycetic dermatitis. The receipt of the printed program showed me that the former is to be well cared for by others at this meeting, and that of blastomycetic dermatitis is soon, I have learned, to be succinctly and thoroughly reviewed by the two gentlemen, Dr. J. N. Hyde and Dr. F. H. Montgomery, to whose labors we owe very largely our knowledge of these cases.

Such being the facts, I thought it unfair to anticipate the contributions of these gentlemen, who have kindly and cordially extended their co-operation toward making this meeting a successful one. I shall therefore take the liberty of departing in a measure from the usual custom, and briefly refer to another subject, which has, especially the last year or two, interested us all—that of vaccinal eruptions. From time to time, it is true, these have received the attention of some of our number or others of our colleagues, more particularly Behrend,¹ Thin,² Morrow,³ Malcolm Morris,⁴ Frank,⁵ Dyer,⁶ Carter,⁷ Sobel,⁸ Allen⁹ and Van Harlingen.¹⁰ Various classifications have been proposed, that by Malcolm Morris being the one most generally accepted, and which has been practically adopted by Crocker, Frank, Van Harlingen and others. Morris divides these cases into two divisions: 1. Eruptions due to pure vaccine inoculation, and 2, eruptions due to mixed inoculations. Frank has modified and enlarged this somewhat, and his arrangement with a few immaterial changes seems to me for the present the most appropriate one. Under this classification we have three divisions:

1. Due to vaccine virus.	Local...	Local erythema. Dermatitis. Local vaccinia. Adenitis.
	Systemic.	More or less generalized erythema (erythema vaccinicum, roseola). Urticaria. Erythema multiforme. Vaccinia (generalized vaccinia). Purpura.
2. Due to mixed inoculation introduced at time of vaccination or subsequently.	Local...	Impetigo contagiosa. Furunculosis. Cellulitis. Erysipelas. Gangrene. Tuberculosis cutis.
	Systemic.	Gangrene. Pyemia. Syphilis. Leptosy. Tuberculosis.
3. Sequelæ of vaccination.		Eczema. Urticaria. Pemphigus. Psoriasis. Furunculosis.

It is true that to some extent these divisions are often more or less arbitrary, as there is some difficulty in

placing some affections on exact etiologic local or systemic relationship. Moreover, it might be open to question as to whether absolutely pure vaccine virus is capable of producing some of the eruptions attributed to it, and this expression, it seems to me, must be accepted in a relative sense. Some of the eruptions named are quite frequently observed, others are much less common, others again are rare, and several are of somewhat questionable relationship. I shall not discuss the numerous affections named, but shall refer only to several of those of special interest. The most frequent and usually more or less evanescent and harmless of these are the localized or general erythema, urticaria, erythema multiforme, a regional vaccinia or vaccinia-like eruption, impetigo contagiosa and a pseudo-erysipelas or erysipelas inflammation or other accidental regional dermatitis. The most important of these, dermatologically speaking, are erythema multiforme, urticaria, pemphigoid eruptions and impetigo contagiosa. The last, which need be but casually mentioned, may present at any time from the date of vaccination till perfect healing has taken place, being most common in my experience toward the end of the first week. It may be slight and practically limited to the region or immediate neighborhood of the vaccinated point, or it may be extensive, and even somewhat generalized. In these latter instances there is a disposition in some cases to bullous development and sometimes a simulation of a pemphigus, but they are less alarming in aspect and of shorter duration and have typical impetigo lesions intermingled. It is not improbable that some of the examples of general vaccinia, the existence of which has been called in question, are instances of moderately developed impetigo contagiosa. Erythema multiforme and urticaria present at any time between the first day and the crusting period, but may, especially the former, appear much later. Behrend believed that there were two periods at which these and most other vaccinal eruptions occurred—in the first three days and not until the eighth or ninth. While this is true to some extent, it is far from being the rule, for there are many exceptions, and the pemphigoid eruptions, to be later referred to, often appear in the third or fourth week, and sometimes one or two weeks after complete healing. Allen and Sobel found urticaria the most common of the generalized eruptions, and occurring between the fifth and fifteenth day, usually the ninth or tenth. It is interesting to note that Allen in the past several years had in a clientele of 10,000 skin cases, mostly children, 600 of vaccinal eruptions, of which 100, or 1 in 6, were of generalized distribution. In my own dispensary practice, which is made up of a fairly large proportion of children, I should say that the most frequent generalized manifestation is a mixed type of urticaria and erythema multiforme, or possibly better described as an erythema multiforme with often itching and other features of urticaria.

The urticaria observed presents practically no special peculiarities from the ordinary type, except that it is apt to be of longer duration and, I believe, shows much more frequently a more marked tendency to vesicular capping, and vesico-bullous and bullous development. This was also noted by Allen and Sobel. In erythema multiforme the erythematous, papular and tubercular manifestations are most common, and as Hardaway¹¹ pointed out the latter are often quite large in size. But the same vesico-bullous and bullous disposition is, however, judged by my experience, likewise noted in these cases, the bullous development especially being

often exhibited, so much so and so predominantly in some cases as almost to entitle them to be classed as vesico-bullous and bullous dermatitis herpetiformis or pemphigus. These latter cases are frequently of long duration. Dyer states as to his experience that in the final dissolution stage of the local sore there may arise varieties of the erythema multiforme group, in any of its types, either singly or combined. In a number of instances he observed the occurrence of a persistent eruption, relapsing over a period of months, and lasting in one instance as long as eighteen to twenty months, and which has in every case been characterized by marked symmetry in distribution and arrangement, and the eruption constantly of a vesicular and bullous type, the lesions varying in size from a pinhead to an orange.

A generalized pemphigoid eruption, relatively uncommon, which is observed to follow vaccination, and which, owing to its alarming characters and possibly gravity in exceptional instances, may give rise to anxiety, is that often presenting the combined features of pemphigus, bullous erythema multiforme and dermatitis herpetiformis, but more especially of pemphigus and dermatitis herpetiformis. I have met with three examples in the past year—two adults and one child—the outbreak developing from two to four weeks after vaccination. Two of these could be clearly classed as acute pemphigus, and the other as a persistent bullous erythema multiforme or a dermatitis herpetiformis. In these three instances the vaccination was what is usually described as a good take, but was somewhat slow in healing, the crust remaining adherent a long time. In one case at the end of three weeks there was the appearance beneath the crust of some purulent matter. In these instances the bullous development was extremely extensive, the distribution in one similar to that of erythema multiforme, but in the others that of a well-developed and extensive pemphigus. There were in all constitutional symptoms of malaise, and occasionally slight febrile action and depression, but nothing more serious, and these were extremely slight and almost wanting in the early part of the outbreak. The eruption in these three cases is still persisting, or, I should say, recurring, but is now somewhat scanty in amount with periods of freedom. They had, up to the time when last seen, so far lasted respectively three, four and eight months. These examples are generally devoid of dangerous characters or fatal ending, but they are sometimes alarming and of possible long continuance. Other somewhat similar cases have been reported under the name of dermatitis herpetiformis by Dyer¹² (1 case), Pusey¹³ (1 case) and Bowen¹⁴ (6 cases). In all these instances the subjects were children under the age of 12, mostly 5 to 7, the eruption first appearing from one to five or six weeks after vaccination, most frequently between the second and third week. In all the eruption was tolerably extensive and of long duration, in several of them still continuing at the time of the report, years after its first appearance. In others, after continuing three to six months, there was lessened activity, and in a few complete disappearance. While these cases are relatively benign in character, exceptional instances of the acute pemphigus type are sometimes of considerable gravity and even of fatal ending. A case in point is that reported by Schamberg and Keech¹⁵ in a female child aged 5, developing ten days after vaccination, and which ran a rapidly fatal course. These observers refer briefly to a second case of acute pemphigus in a boy aged 8 following two weeks after vaccination. These various bullous eruptions of the types

just described, while not numerous, are sufficiently frequent to justify the assumption of an etiologic relationship. It is particularly in connection with these cases that the observations and study of the etiology of acute pemphigus by Pernet and Bulloch¹⁴ are of great interest. In their report and analysis of cases in a number of instances the subjects were butchers and the disease had originated from a small wound resulting from their occupation. They report one instance of a pemphigoid eruption which apparently followed inoculation from a similar eruption on the teats of a cow. They also mention other examples where the disease occurred in those having to do with animals and animal products, and instances of the existence of a pemphigus eruption in animals are likewise referred to. I believe these observations may have a distinct bearing on the etiology of some of the eruptions of vaccination, but especially those of the pemphigoid type. The subject is certainly worthy of consideration and investigation.

Exclusive of the eruptions referred to other cutaneous manifestations, excepting the conditions often limited to the region of vaccination, and which need not be specially referred to, are somewhat rare. Eczema developing at the inoculation site or arising on other parts occasionally follows, but probably only in those with a clear eczematous tendency. The possibility of a marked or more than temporary aggravation of an existing eczema as the result of vaccination is, according to my observation, so slight that it should not be considered a bar to this operation. I have, in fact, noted in several instances that amelioration followed vaccination, and in one instance in a chronic case a disappearance of the eczema. Duhring, Tait and others also attest the occasional curative influence in these cases. Colcott Fox noted, in his service in which there were many children, that there was practically no relationship between vaccination and the development of eczema, and believes that this apparent occasional relationship is simply owing to the fact that eczema is common in those under the age of 5, at which time vaccination is usually practiced. He believes eczema just as frequent under this age in those unvaccinated.

Another generalized disease which has in rare instances taken its start at the point of vaccination or has made its first appearance after this operation, is psoriasis. Klamann,¹⁷ Campbell,¹⁸ Rohe,¹⁹ Piffard,²⁰ T. F. Wood,²¹ Hyde,²² Gaskoin,²³ Chambard,²⁴ Rioblanc²⁵ and others have recorded such examples, some of which were stated to be in families in which psoriasis had never existed, or at least had not yet appeared. Some of these observers, however, did not consider its appearance more than coincidental. Its occurrence is so exceptional that the latter conclusion seems justified, an assumption of an etiologic relationship scarcely being warranted. The operation may, it is true, by its action as a local or general excitant or by its disturbing influence on the nervous system, be a factor, but even this probably only in those who have a distinct tendency to psoriasis. Van Harlingen seems to have been the only one who has made methodical observations as to the influence of vaccination on the course of previously existing affections of the skin. He states:

During the smallpox epidemic of 1872 I observed all cases of skin disease coming under my notice in which vaccination had been practiced. In a few, some aggravation of the symptoms followed; in others an apparent improvement took place. But in the great majority of cases vaccination did not appear to exercise any influence whatever on the course of the more common diseases of the skin coming under observation. Dur-

ing the present epidemic I have had all the cases of skin disease coming under my notice at the Children's Hospital and in private practice vaccinated so far as I have been able, but the results are about the same as those observed thirty years ago.

Irrespective of the usual transitory rashes, the urticarias, and the erythema multiforme, and the more alarming bullous eruptions, it has been believed ever since the operation of vaccination has been advocated that the process is not without danger as to the inoculation of other more serious diseases, and with careless operators and impure virus the accidental inoculation of tuberculosis, syphilis, leprosy and other affections is not beyond the range of possibility. In fact, as regards tuberculosis, suggestive cases have been recorded by Besnier,²⁶ Perry,²⁷ Little²⁸ and a few others, in which localized integumentary tuberculosis—*lupus vulgaris*—has developed at the point of vaccination. That much being admitted general infection might likewise be produced. A case under my observation of development of *lupus* at the site of vaccination and immediately following the same, is another in point. This patient and two others were vaccinated from the same crust; the reactionary local symptoms in all were severe, in two quickly followed by general symptoms of what seemed as described to me of mixed tuberculous and septicemic character, followed by death. In my patient, at that time a robust young female child, it was followed by the development of *lupus* which had persisted and gradually extended till when I saw her ten to twelve years later it involved an area as large as the palm. The history of the cases was given to me by a physician, the brother of my patient, but owing to the years which had elapsed and the nature of the accident, further details could not be obtained, and there naturally remains an element of doubt about the true character of the condition which carried off the other two.

Examples of syphilis inoculation through vaccination are rarely observed at the present day, and then only through gross carelessness or through pure accident unconnected with the procedure itself; but that it was formerly, while not frequent, occasionally noted, is shown by the observations of Hutchinson, Fournier, Taylor and others. As to the accidental inoculation of leprosy there has long been a belief that such has often occurred, but unquestioned examples are hard to find, and Baum²⁹ was not able to collect any reliable evidence on this point. Daubler's³⁰ two cases are suggestive. Arning³¹ cites an instance of an increase of leprosy in a certain district, called Lahaina, on the Island of Mani, following a year after somewhat extensive arm-to-arm vaccination, but beyond an unusually large development of leprosy cases in a place comparatively free from the disease, there was no positive data to prove the relationship. This observer has demonstrated the presence of *lepra bacilli* in the vaccine lymph taken from a leper, and this tends to show the possibility of such accident in leprosy countries if human virus were used from an unsuspected subject with the malady as yet in an unrecognized state. If, however, the intermediate host theory of the *lepra bacillus* is found tenable, a view now somewhat in favor, such accident would be clearly impossible. In fact, since the practical disuse of human virus such constitutional maladies as leprosy, syphilis and the like can scarcely occur at the present day.

In vaccination, as in any other operative procedure, care, caution and cleanliness are essential prerequisites to safety, and with the proper observance of which the

operation with possibly few exceptions is an absolutely harmless and safe one. It is doubtless true that in some of the exceptional serious accidents of vaccination that neither the operator nor the virus is at fault, but that the damaging infection takes place later as a result of carelessness, negligence and uncleanness on the part of those vaccinated. Moreover, in many instances of eruptions occurring during or immediately subsequent to vaccination it is more than probable that they are purely coincidental, and in no way connected with or due to this procedure, either primarily or through accident secondarily. The layman, and flagrantly the anti-vaccinationists, and sometimes the physician, too, are too prone to consider all eruptions at such times as effects. In short, it should be clearly understood that eruptions occurring at such period are not necessarily vaccinal, although it is true that many of them are. It is clearly unwise and unscientific, however, even for the laudable purpose of quieting the fears of the public or for the purpose of withholding ammunition from the anti-vaccinationists, to deny that vaccination is ever responsible for any eruptive or systemic disturbance. Nothing is to be gained by smothering, concealing or perverting facts. The candid recognition of exceptional complications should lead to a study of their causes, and finally, in all probability, to their prevention or at least to their diminution. In those eruptions commonly observed—urticaria and the various types of erythema multiforme—I believe it is probable that the causative factors lie with the virus itself, either to its preparation or preservation, and possibly due to some admixture or changes in the lymph constituents, and not necessarily of extraneous origin. This seems borne out by the facts that the serums used in the treatment of certain maladies will likewise often produce similar rashes. It is well known that the serum from the horse used in the manufacture of antitoxin will provoke these eruptions, but—and this is the point which it seems to me has a pertinent bearing—according to Berg,³² much less frequently when the serum is thoroughly and carefully filtered. It appears, moreover, extremely probable that the pemphigoid eruptions are likewise due to some toxin or microbic element derived directly from the animal from which the virus is obtained. It is in this direction, then, I believe, that the etiologic causes in the production of some of these various rashes must be sought. But even taking into consideration the exceptional accidental more serious eruptions, their occurrence weighs as nothing as compared to the benefit which vaccination has bestowed on mankind. But with proper care, however, on the part of the caretakers of the cattle, vigorous governmental inspection of the animals and extreme precaution in the collection and preservation of the vaccine, there would be but little to fear. Add to this caution and cleanliness on the part of physician and patient, both before, at and after the time of the operation, till complete healing has taken place, and the occurrence of serious accidents would be practically placed very nearly beyond the bounds of possibility.

THE DECENTERING OF LENSES FOR NEAR WORK.*

G. C. SAVAGE, M.D.

Professor of Ophthalmology, Medical Department of Vanderbilt University.
NASHVILLE, TENN.

The ideal position of lenses, when there is perfect muscle adjustment of the eyes, is such that the visual axes may cut their optical centers, and that the planes of the lenses may be parallel with the equatorial planes of the eyes. When the visual axes cut the optical centers of the lenses there can be no prismatic effect; and when the plane of the lens is parallel with the equatorial plane of the eye there can be no cylindrical effect. A want of parallelism between the plane of the lens and the equatorial plane of the eye means that there will be a cylindrical effect, for, as is well known, the strength of the lens, at right angles to the axis of tilting, is increased, while along the axis of tilting its power is unchanged. Tilting a lens 45 degrees practically doubles its refractive power for the rays that are in a plane at right angles to the axis around which it has been rotated. These laws apply with equal force to lenses that are worn for distant seeing and those that are used in near work. Infringement of these laws constitutes the chief objection to bifocal lenses. If it can be estimated just how much the visual axes must be depressed below the extended horizontal plane of the head, in reading or doing other near work, through the same number of degrees the upper border of the lenses to be used should be tilted forward to prevent cylindrical effect vertically; and each lens should have its nasal border tilted backward to the extent of half the angle of convergence, to prevent cylindrical effect horizontally. This double tilting would make the plane of each lens parallel with the equator of the eye before which it is placed.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, U. V. Würdemann and J. A. Lippincott.

But the subject assigned me by our chairman is "The Decentering of Lenses for Near Work," and to this subject the remainder of this paper will be confined.

1. If there is orthophoria, presbyopic lenses should be properly centered, that is, they should be so placed that each visual axis will cut the optical center of its lens, when a point of fixation is in the extended median plane of the head. On changing the point of view in any direction, without moving the head, the prismatic effect would be the same in kind for each eye, and if the lenses are of equal strength, the degree of prismatic effect would be the same for each eye. The lenses for such eyes should never be so placed that both visual axes would cut them on either the nasal or temporal sides of the optical centers. With safety, and in some cases with positive helpfulness, the lenses may be so placed that the visual axes would cut them directly above the optical centers. As can be readily seen, this would take some work off the subvertor muscles, thus lessening the demand on the second and sixth conjugate brain centers. But orthoptic eyes will not take kindly to presbyopic lenses placed so high that the visual axes would cut them below the optical centers, for this would create an abnormally large demand on the two centers mentioned.

2. If there is uncomplicated esophoria, both presbyopic lenses should be decentered directly out, and to an equal extent, so that the two visual axes may cut the lenses to the nasal side of their optical centers, thus favoring the weak externi. This can be accomplished equally as well by making the frames wider than called for by the pupillary measurement. If the interni are properly attached, the compensating esotropia will be attended by relief, but if attached too low the compensating esotropia would develop a plus cyclophoria that might bring great discomfort. To decenter lenses in, or to have the frames narrower than called for by the pupillary measurements, for such eyes, would render the lenses more or less unbearable.

3. In esophoria complicated only by hyperphoria of one eye and cataphoria of the other, the decentering of presbyopic lenses should be confined to the lens for the hyperphoric eye, and should be down and out, so as to develop a compensating eso-hypertropia of this eye. To decenter the lens out-and-up for the cataphoric eye would result in developing a plus cyclophoria, to correct which the superior oblique would be forced into a state of abnormal tension. Slight abnormal tension is well borne by the inferior oblique, but not by the superior oblique.

4. In esophoria, complicated by hyperphoria of one eye and cataphoria of the other, with plus cyclophoria, the decentering of presbyopic lenses should be confined strictly to the lens for the hyperphoric eye, and should be down-and-out, so as to develop a compensating eso-hypertropia. The rotation in-and-up, made necessary by the prism displacement, generates a minus cyclophoria which, in such a case, would neutralize the existing plus cyclophoria, thus enabling the superior oblique to easily parallel the vertical axis of the eye with the median plane of the head. In such a case the evil-effect of decentering the lens out and up, for the cataphoric eye, comes from the compensating eso-catropia, and is due to the plus cyclophoria that is thus generated. There being already a plus cyclophoria which the superior oblique must correct by being kept in a state of abnormal tension, the added artificial cyclophoria can do nothing but augment the discomfort of the patient.

5. In simple exophoria each presbyopic lens should be

decentered directly in and to an equal extent, or what would be the same in effect, the frames should be made narrower than would be indicated by the pupillary measurement. This would develop a compensating exotropia, and the lenses would be well borne if the externi have ideal insertions or if their insertions are lower than normal; but if their insertions are higher than normal the lenses thus decentered would not be well borne for the reason that the compensating exotropia would develop a plus cyclophoria. Presbyopic lenses, in frames that are wider than indicated by the pupillary measurement, can not be borne by an exophoric.

6. In exophoria complicated by hyperphoria of one eye and cataphoria of the other, the decentering of presbyopic lenses should be confined to the one for the cataphoric eye, and should be in-and-up. This would develop a compensating exo-catropia; that is, the eye would be rotated out-and-down. Every such rotation of an eye develops a minus cyclophoria which the inferior oblique can correct easily. Decentering the lens in-and-down, for the hyperphoric eye, would cause a compensating rotation out-and-up, which would develop a plus cyclophoria, the correction of which would not be easily borne by the superior oblique.

7. In exophoria complicated by hyperphoria of one eye and cataphoria of the other, with plus cyclophoria, the decentering of the presbyopic lenses should be confined strictly to the one for the cataphoric eye, and should be in-and-up. The compensating exo-catropia, that is, the rotation out-and-down, would develop a minus cyclophoria which would more or less completely neutralize the existing plus cyclophoria. To decenter the lens for the hyperphoric eye in-and-down would cause a compensating exo-hypertropia, that is, a rotation out-and-up. This would develop artificially a plus cyclophoria which, grafted onto the plus cyclophoria already existing, would only add to the discomfort of the sufferer.

8. In hyperphoria of one eye and cataphoria of the other, with or without plus cyclophoria, the decentering of presbyopic lenses should be confined to the one for the hyperphoric eye, and should be directly down. There would be caused a compensating hypertropia. This would develop a minus cyclophoria which the inferior oblique would counteract readily. To decenter the lens directly up for the cataphoric eye would cause a compensating catropia which would develop a plus cyclophoria not easily correctible by the superior oblique. The trouble with such a lens would be emphasized if the artificial plus cyclophoria should be grafted onto an existing plus cyclophoria.

9. In double hyperphoria uncomplicated, both presbyopic lenses should be decentered directly down, and to an equal extent; or, what would be the same in effect, the nose-bridge should be made deep enough to allow the visual axes to cut the lenses above their optical centers.

10. In double cataphoria uncomplicated, if any decentering should be done at all it should be directly up.

11. If there is plus cyclophoria only, in a presbyopic case, both correcting lenses should be decentered down.

The decentering of lenses, or prisms in positions of rest, is only one way of dealing with muscle errors. I believe the rules given above are scientific, and that, if followed, comfort from the lenses will be experienced, provided the prismatic effect is not too much. The maximum vertical prismatic effect should be placed at one degree, certainly not more than two degrees, and the maximum lateral prismatic effect should be placed at two degrees, certainly not more than four degrees. In the

greater number of cases the prismatic effect should correct about one-half the manifest error, but in some cases a full correction, especially of a small vertical error, may be given.

Prisms and decentered lenses interfere with some of the visual judgments and therefore are objectionable. For this reason it is better to cure muscle errors of low degree by proper prismatic exercise. Muscle errors of high degree should be treated surgically.

THE GENESIS AND TREATMENT OF THE MYOPIC EYE.*

S. D. RISLEY, M.D.

ATTENDING SURGEON WILLS DYE HOSPITAL,
PHILADELPHIA.

There is no more interesting or important chapter in ophthalmology than that which treats of the etiology, nature and treatment of the myopic eye. The widely differing views which have been expressed regarding each of these points seem to justify a renewed presentation of the subject.

HISTORY.

The observations made in the early part of the century by James Ware regarding the relatively greater prevalence of myopia among the educated portions of the community were verified by the later examinations in the schools by many observers, who demonstrated its steadily increasing percentage as the children advanced in age and school progress. Since this was associated with a nearly equal fall in the percentage of hypermetropic eyes it required but a step to the seemingly logical conclusion that the small hypermetropic eyeball of childhood increased in size with the physiologic growth of the child into emmetropia and from this into the large myopic eyeball; in a word, that the myopic eye was a physiologic evolution. Closely allied to this was the proposition that, since only those eyes which are subjected to the demands of civilized life were observed to undergo this change of refraction, therefore it was the eye of civilization, a species of social evolution, an adaptation to the act of work.

More careful observations of the conditions, however, revealed the fact that these conclusions were untenable, since they must be maintained in face of well-known and characteristic pathologic conditions associated with myopia, which imperiled the integrity of the eye, e. g., posterior staphylomata, choroidal atrophies at the temporal border of the optic nerve and in the region of the fovea, a fluid, i. e., a degenerate vitreous with floating opacities and frequent detachment of the retina, all of which sustained with myopia an intimate and undoubted relation of cause and effect. Increasing experience and painstaking observation have served, after nearly half a century, to maintain and enforce the truth of the early teaching of Donders, to the effect that the myopic eye is a diseased eye.

Accepting the proposition as stated, it is obvious, therefore, that myopia can not be regarded as either a physiologic or sociologic evolution, but is to be viewed as one of the many baneful results of civilized life over the physical well-being of the race. The problem presented for solution is its prevention.

GENESIS OF THE MYOPIC EYE.

The observations of Cohn and others showing the rapidly increasing percentage of the disease during the

educational process led thoughtful observers to inquire into its cause. Since it was evidently in some way closely related to the work in the schools it was ascribed to the bad hygienic environments of the school room, and an era of improvement was inaugurated in the lighting of the school houses, the arrangement and construction of desks and seats, the paper and type used in school books, etc. A few years later a re-examination of the same children under the improved conditions of work, much to the disappointment of these industrious and careful observers, discovered no notable diminution in either the percentage of increase or in the arrest of the progress of the myopia in those already myopic at the first examination. It was obvious, therefore, that some hitherto unnoticed factor was responsible for the genesis of the myopic eye.

The earliest suggestion with which I am familiar of the possible relation between astigmatism and myopia was made by Dr. Green¹ of St. Louis in 1867, and again² in a paper in 1871. He closes the latter paper with the statement that so far as he knew statistics of large numbers of eyes to establish the frequency of astigmatism were wanting. My own statistics collected in the Philadelphia schools, 1878 to 1881, were, so far as I know, the first to establish the truth of Dr. Green's suggestion, of which I was at the time entirely ignorant. In 1880 I published³ a group of cases which, while under observation, had passed from hypermetropic into myopic astigmatism without at any time becoming emmetropic. That is to say, they passed through the turnstyle of astigmatism from hypermetropic to myopic refraction. They were all asthenopic, and the increase of refraction was associated with disease of the intra-ocular tunics. This publication was followed in 1881 by the report of the school statistics,⁴ which revealed a group of interesting and important facts bearing on the genesis of the myopic eye.

First. The emmetropic eye not only remained in a nearly uniform percentage through all ages of school life, but enjoyed the highest acuity of vision and was relatively free from pain and disease.

Second. The eyes with a simple hypermetropia stood next to emmetropia in all these respects.

Third. The eyes with hypermetropic refraction, especially where astigmatism was present, manifested symptoms of asthenopia, lowered acuity of vision and pathologic states of the fundus; notably irritative and absorption changes throughout the fundus, granular changes at the fovea and crescents of choroiditis at the temporal margin of the optic disc in all stages of development from a faintly outlined crescent to far advanced atrophies which had before been regarded as physiologic anomalies when seen in hypermetropic eyes, but as pathologic if associated with myopic refraction.

Fourth. It was shown, as had been demonstrated by all observers, that not only did the myopic eye increase in percentage during school life, but that there was a closely corresponding diminution in the percentage of hypermetropia. This group of facts seemed to afford a sufficient demonstration for the conclusion that the myopic eye, with its characteristic pathologic changes in the fundus, was but a later stage of the conditions witnessed in the eyes with hypermetropic astigmatism, hence that the former was recruited from the latter.

Fifth. In the very large percentage of congenitally

defective, that is to say, eyes with hypermetropic astigmatism which were shown to exist in the schools, we have, therefore, a sufficient explanation for the steadily increasing percentage of myopia notwithstanding the improved environments of the school room.

This was essentially a new view of the subject of myopia. The question of heredity resolved itself into a hereditary transmission of the anatomical defect on which the underlying pathologic conditions resulting from eye strain depended and which, in turn, led to the impaired nutrition of the ball and the distention of its coats. The malformation of the eyeball, that is to say, astigmatism, and the faulty binocular balance so frequently observed in astigmatic eyes, doubtless sustain a very important relation to certain distortions of the skull and abnormalities in the shape and size of the bony orbit. We have, therefore, primarily a congenital anatomical anomaly as the starting point or basis for the chain of events we have been considering. The truth of these propositions finds marked confirmation in the daily routine of office work, where we much more frequently find the children of myopic parents with hypermetropic astigmatism than with myopia, which, if carefully corrected, removes the asthenopia and associated conditions which are the starting point for the myopic eye. Indeed, it is, in my experience, extremely rare to find a myopic eye before the school age.

TREATMENT OF MYOPIA.

The treatment of myopia should therefore be conducted with this chain of events in mind. In a word, it should be begun before myopia is established. I have already shown⁶ that in 200,000 eyes corrected by glasses in Philadelphia in twenty years, that the number of eyes with myopic refraction applying for relief fell from 28.43 per cent. in the first period to 16 per cent. in the last, a diminution of approximately 50 per cent. It is apparent, therefore, that our highest duty is in preventing the disease. It was to this end that in 1881 I first urged the importance of examining the eyes of every child at the beginning of the educational process in order to determine if the eyes were fitted to safely undertake the strain of school life. Unfortunately, the myope is with us and requires at our hands the highest skill and solicitous care to ward off its baneful results.

It is obvious from the foregoing conclusions that treatment resolves itself into two factors: First, attention to the pathologic conditions; second, the careful correction of the anomaly of refraction and accommodation and any of the associated abnormalities of ocular balance.

I wish at the outset to urge that no final attempt should be made to prescribe correcting glasses until the fundus conditions upon which the progressive near sight depends shall be brought under control. To this end the following routine treatment has in my own hands been of value. Complete rest from all near work, the steady and persistent use of a mydriatic, protection from light by smoked glasses, the temporary abandonment of the accustomed correcting glasses, the internal administration of the so-called alterative drugs, e. g., potassium iodid and bromid with the bichlorid of mercury, iodid of iron, etc., and the careful attention to the general regimen. This method will usually lead to a more or less speedy relief from the asthenopia and to marked improvement in the condition of the uveal tract. Then, and not before, a careful and painstaking study should be made of the refraction of each eye separately. It is by no means

an easy task to determine accurately the exact static refraction at the macula in high myopia. Therefore, not only patient subjective study with glasses and test cards, etc., should be employed, but the results so obtained should be checked and verified by the objective methods we now have at command.

It is very easy, indeed, to overlook the lower grades of astigmatism, especially if the corneal meridians are heteronomous, a very common condition in myopic eyes. The static refraction of each eye having been determined, we can now for the first time, with any degree of accuracy, study the state of the binocular balance. This should be done with carefully centered correcting glasses, placed in some fixed form of apparatus, the eyes being maintained in the primary position. When studied in this way we soon learn to revise many of the views formerly entertained regarding the mobility of the myopic eye. The great frequency with which a dark ruby glass, or the multiple Maddox rod, or some other suitable device, will reveal a faulty binocular balance, was to me at first a great surprise, but not more so than the promptness with which the asthenopic and irritation symptoms disappeared when this was corrected, either by a glass or by tenotomy in suitable cases. This, however, is to be expected when we consider the essential anatomical basis or origin of both the astigmatism and the faulty attachment of the muscles of the globe.

In the higher grades of astigmatism not only are the corneal meridians likely to be heteronomously placed, but it is comparatively rare not to find an absolute heterophoria due to the faulty attachment of one or more of the ocular muscles.⁶ It is in this fact and to the associated anisometropia rather than in the large ball that we find adequate explanation for the recognized difficulty of binocular vision in many cases of high myopia. It is important in the determination of the ocular balance to avoid deception growing out of the presence of eccentric fixation in one or both eyes caused by small, partial or complete, macular scotomata, so common in high myopia.

I have seen many cases of progressive nearsight in which the tendency to progression, the asthenopia and the choroidal disease were rebellious to all treatment and to the most careful corrections of the anomaly of refraction until the binocular balance was corrected, either by suitable adjustment of prisms or by tenotomy or advancement of the faulty muscles. Many illustrations and instructive examples would be cited if time permitted.

Should full correcting glasses be worn in high myopia? I invariably prescribe full correcting glasses for myopia of 12 D. or less, but if the myopia is higher than 4 or 5 D., under correcting glasses are given for near work, the allotted far point chosen depending upon several factors, e. g., the age of the patient, the power of convergence and the nature and the amount of work required; the condition of the fundus and the tendency to progression of the disease. When the tendency to progression is marked the full correcting glasses are allowed only out of doors, the undercorrecting glass to be worn constantly in the house until the progression is arrested. In many cases bifocal glasses are ordered. If the convergence is weak or painful, a prism, base in, is secured by decentering the glasses or by having the near work glasses ground on a prism with base in, or a somewhat stronger glass is given. If esophoria is present at 6 m. a weaker glass is prescribed, so that all near

work is done at the remote point of the glass, and thus all strain taken from the accommodation, which relieves the tendency to undue convergence. In myopia of 15 D. or higher a full correcting glass is rarely desirable or safe and usually is not well born at any age, certainly not when the usually critical fundus changes are present. For such patients I usually prescribe a glass for constant wear, deducting from 3 D. to 5 D., and allow a lorgnette of 3 D. or 5 D. to be placed in front of the under-correcting glasses temporarily when the full correction of the myopia is necessary or desirable to secure accurate distance vision.

RESULTS OF TREATMENT.

What have been the results of these methods of treatment? I have a long list of myopic patients who have been under more or less continuous observation for many years, some for twenty years or more. I have witnessed during these years many instances of separation of the retina, but they have occurred, with but three exceptions, in patients who came for the first time because of this unfortunate accident.

In these exceptions one, an eminent physician with astigmatism = 3 D. in each eye and an additional myopia of 20 D. in the right eye and 18 D. in the left, was knocked down by a bicycle and rose with detachment of the retina in the right eye, which was rapidly followed by opacity of the lens. The left eye became irritable after this accident and slowly developed a small macular atrophy. He had been under my personal observation and care since 1875.

The second exception, a German, aged 49 years at the time of his accident, a head bookkeeper for a large manufacturing firm, had high astigmatism and myopia of 12 D. He had been under treatment for eight years without increase of myopia and had pursued his work without difficulty. After an absence of two years, during the latter part of which he had been in impaired health and had suffered much from headache and weak eyes, he returned with a separation of his retina on the right side, which had come on suddenly the day before after reading late into the night. He was placed in a recumbent posture, atropia instilled and a compressive bandage applied. Under this treatment the detachment was slowly reduced and V. rose to 6/9. This continued for several weeks and he returned to his counting room, but not to work. He started from his home to my office and on the way noted in the cars that he was able to read a printed postal card with the injured eye alone. Reaching the city he ran a short distance and sprang onto a moving street car. The vision at once became blurred, and I found on his arrival at the office that the detachment had recurred.

In the third case detachment had occurred in the left eye when first seen, and in a few months occurred in the right in spite of treatment. Here also there was high astigmatism and additional myopia of 17 D. He was a professor of mathematics, busily engaged in his class work, a hard student, and, as he had a large family dependent upon his salary, refused to abandon his work even temporarily. His choroiditis progressed, a macular hemorrhage occurred and was speedily followed by extensive retinal detachment and blindness. With these exceptions I have seen no retinal detachment occur in my practice among patients under treatment. Macular atrophies which had not already occurred when first seen have been comparatively rare. I have seen no case of myopia progress under my own observation beyond 7 D., and but one of these. Any progression after the

first treatment and correction has been exceptional, and could then usually be ascribed to some imprudence upon the part of the patient, e. g., the neglect of the near work glasses or an inordinate amount of work. A number of cases of increased refraction have occurred after attacks of severe general disease.

These views could be exemplified by many illustrative cases. The following presents many interesting features:

CASE 1.—T. H. P., school boy, aged 8, was brought to me from the interior of Pennsylvania in March, 1879, suffering from weak and red eyes, headache and vision reduced to 1/10 in the right and 1/5 in the left. His mother who accompanied him and a sister aged 6 both had hypermetropic astigmatism. The father was deceased and the state of his refraction unknown. The sister's eyes were studied carefully, revealing a honeycombed choroid and a yellowish crescent of choroiditis at the temporal margin of both nerves. She often complained of headache. The eyes watered in the sunlight and became flushed. Treatment and correction of the refraction error was advised but the advice neglected. She was not seen again until 1898, nineteen years afterward, when she came under treatment with myopic astigmatism and a posterior staphylomata in both eyes.

In the boy the ophthalmoscope revealed an apparent myopia of 4 D. in the right eye and 3 D. in the left. He had a broad yellowish crescent in both eyes and the choroidal stroma was visible in large areas throughout the fundus. After the prolonged use of atropia he received for constant wear —1.50C—1c. ax. 20° in the right and 160° in the left which gave V.=20/LXIV in each eye not improved by a stronger glass. He returned in June, 1881, at the close of his school year with vision reduced with his glasses to 20/160 in the right and 10/200 in the left. The fundus changes had greatly increased. He then received the iodid and bromid of potassium internally and atropia was used three times daily for two weeks. He would then accept no change in the right glass, but vision rose to 20/40. On the left the myopia had increased to 2 D. The astigmatism remained as before. He was not seen again until 1896, fifteen years after. He was then driven from work as a clerk by his bad eyes and headache. He had in the meantime been under advice of a local surgeon, who had given him successively stronger spherical glasses until at the time he was wearing —5 D. sp. before the right and —6 D. sp. before the left, both for distance and for reading. With these V.=6/XV. The astigmatism had been neglected. He had blephorospasm and frequent attacks of violent sick headache. There were large posterior staphylomata, macular disease in both eyes with fluffy fundus and absorption areas. A mydriatic and smoked glasses were once more prescribed together with complete rest, and alteratives internally. These were continued for two weeks, when he selected the following glasses: O.D.—4.00C—1.50c. ax. 30° V.=6/VII½, O. S.—5.00C—2.00c. ax 150° V.=6/IX. He then returned to his work with an undercorrecting glass for reading and writing, but the headache speedily returned and vision fell in less than a month to 6/XV and 6/XXIV. A mydriatic was again instilled and while waiting in the office V. rose to 6/VII½ and 6/IX respectively. A careful study of the ocular balance showed an esophoria =10° at 6m. and a right hyperphoria of 5°. After sitting with the vertical prism and his correcting glasses the esophoria disappeared. He wore a trial prism for a week and returned without headache and no diminution in his acuity of vision. I then did a tenotomy of the right superior rectus, correcting accurately the vertical deviation. He returned in a month to his clerical work. His eyes remained weak for several months but gradually improved in all respects both in ability for work and in the fundus conditions. There has been no tendency to increase of the myopia and for five years he has pursued the arduous duties of a clerk in a railroad office free from any serious trouble.

Several points are illustrated by this young man's experience. In the first place, the repeated value of the therapeutic treatment by mydriatics, etc., but notwith-

standing this the steady advance of the myopia until both the astigmatism and hyperphoria had been corrected. Second, the evil of ordering, carelessly, successively stronger spherical glasses to improve the distance vision. Third, that in the presence of imperfect binocular balance the most carefully chosen glasses correcting the astigmatism did not secure his safety or comfort; and, finally, the arrest of the disease by correcting the ocular balance and by the careful correction of the anomaly of refraction. Time will not permit any extended discussion of many important points, but one must be noted, viz.: The importance of an under-correcting glass for all near work, and a full correcting glass for distance, both of which shall provide a common far point for each eye.

DISCUSSION.

DR. EDWARD JACKSON, Denver—It is, of course, impossible, and I suppose not desired, to attempt any complete discussion and review of this extremely interesting and valuable paper. I shall only take up, therefore, a few scattered points. With reference to the genesis of high myopia, in all of the cases that I can now recall, seen in early childhood, it has happened that there has been nothing pointing to heredity. I have seen comparatively few cases of high myopia in young children, but it happens that none of them had myopic parents. They did show, however, marked evidence of ill-health, disturbance of nutrition; and it seemed to me that was an important factor in the genesis of their myopia. I am also inclined to think it is important from the fact that the most rapid increase of myopia I have watched has occurred after some temporary severe impairment of the general health and nutrition.

There can be no doubt that the development of myopia during school life is common, and myopia developing in that way has two causes: one, the congenital defects, including astigmatism and possibly malformations of the orbit and attachment of ocular muscles; the other, the close work of school-life, and the use of the eyes under unfavorable conditions. We do not see in young people not exposed to school life the same development of myopia. Near work is one of the elements. Myopia in general may be taken as developing from these congenital defects and near work. In high myopia I believe an additional factor comes in in the use of the eyes under the conditions under which uncorrected myopic eyes must work.

My experience points to the importance of the careful correction of the refraction as a means of preventing the development of high myopia; that if that is attended to the myopia never becomes very high, unless it has already reached pretty nearly the limit before the correction is applied. Generally the progress ceases with full correction. It remains stationary for a time while there may be some change in astigmatism. But if change is once started so that the correction becomes imperfect, the myopia increases.

In the treatment, laying aside the correcting lenses for a time is important if the lenses are not the proper ones. Lenses should be laid aside until the correct ones can be determined. But, as soon as the correct lenses can be ascertained, the patient is better off to wear them. It may be wise to continue the mydriatic in some cases, but the correcting lens should be put on as soon as it can be ascertained.

With reference to the partial correction for near work, under Dr. Risley's teaching I practiced that for some time, but in time gave it up. While I feel that it is necessary in very exceptional cases, I think the better rule is to give the full correction for everything. I think the full correction, by encouraging the child to use the eyes more for seeing distant objects, is an extremely important means of influencing him to adopt those occupations that are not so likely to produce increase in the myopia. I feel about giving a partial correction for near work a good deal like Professor Haab feels about having a small size of magnet. If you give full correction the patient uses the eyes to the best advantage.

I would like to call attention to the literature of the past year on the subject, particularly the series of cases reported from Germany, by Pfalz and Heine before the Heidelberg Congress. Pfalz gave three series of cases, one of undercorrection, one of partial correction for near work, and one of full correction for near work. There were about 18 to 25 cases in each series. In the first two series there was but one case in which the myopia did not increase. In the third series, in which the full correction was worn constantly, the percentage that increased was extremely small. The discussion that followed the reading of these papers is still more remarkable, for not one raised his voice in defense of what we have regarded as the old German teaching, but all endorsed more or less completely the use of the full correction.

DR. RISLEY, in closing—I am obliged to Dr. Jackson for bringing out in the discussion the subject of full correcting glasses in myopia. In my paper I urged the wearing of under-correcting glasses only indoors and then only where the tendency to progression was marked. Notwithstanding the views expressed by Dr. Jackson, my opinion is in favor of using under-correcting glasses for near work and indoors in progressive myopia, otherwise there is almost sure to be headaches, discomfort and increased tendency to progression. I have but rarely seen any increase in the myopia when patients have been faithful to the undercorrecting glasses for near work. One other thing that I possibly did not make quite clear is that glasses should be carefully decentered, or ground on prisms with their bases in, certainly where exophoria is present and in extremely tender eyes where the strain of convergence at the near point is painful.

THE NEED OF CORRECTING AMETROPIA AFTER MIDDLE LIFE.*

C. M. CULVER, A.M., M.D.

ALBANY, N. Y.

The Century Dictionary says that "By a middle-aged man is generally understood a man from the age of 40 to 50." Presbyopia is usually supposed to begin between the ages of 40 and 46, although, with Donders' liberal definition of presbyopia, it may be present at the age of 30 years. Presbyopia, of itself, is properly treated by the wearing of an artificial substitute for the quota of accommodation that has been lost, because of the diminution in the elasticity of the crystalline lens—a diminution incident to advancing age. Convex lenses or an equivalence of their optical power in cases in which lenses need to be used for the correction of ametropia, constitute such substitute for lost accommodative power. This being true, it is primarily essential that concomitant ametropia receive due attention, when glasses for the relief of presbyopia are chosen, the effect of such attention having the form of modification of the strength of the lenses selected.

A common experience of the average oculist may be typified by a hypothesis of a patient whose eyes are hyperopic by one dioptre and whose age is 50: his near-work glasses have collective power, each, of two dioptres: he is fairly robust and wore no glasses till 47 years old, having avoided near-work as much as possible until it became inevitable, when he reluctantly yielded to invincible fate and bought these "No. 18" glasses of his jeweler or grocer. The vendor had a table, gotten at the same time with the sign: "Eyes examined free" and has not dared to go beyond "No. 18" in the case of a customer whose age was not greater than the figures opposite "No. 18," and whose spasmodic accommodation enabled him to read, for the length of time of a "free

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, H. V. Wurdemann and J. A. Lippincott.

that in this disease some die in whom most of the symptoms are comparatively mild, while others recover in spite of extremely grave conditions:

PULSE RATE.	RECOVERED.	DIED.	TOTAL.
100 to 115.....	80	17—17 per cent.	97
115 to 130.....	80	47—37 per cent.	127
130 to 145.....	25	31—59 per cent.	56
145 and up.....	2	21—91 per cent.	23
TEMPERATURE.	RECOVERED.	DIED.	TOTAL.
99 to 103.....	78	48—38 per cent.	126
103 to 105.....	106	52—33 per cent.	158
105 to 106.....	20	12—38 per cent.	32
106 to 107.....	2	5—71 per cent.	7
107 to 108.....	0	4—100 per cent.	4
RESPIRATION.	RECOVERED.	DIED.	TOTAL.
20 to 35.....	73	17—19 per cent.	90
35 to 45.....	92	41—30 per cent.	133
45 to 60.....	40	51—56 per cent.	91
60 and up.....	2	13—87 per cent.	15

The majority of fatalities occurred in the first ten days. The duration of the disease in the cases that recovered or died, so far as shown by the records, was as follows:

DURATION.	RECOVERED.	DIED.	TOTAL.
1 to 10 days.....	11	48—81 per cent.	59
10 to 15 days.....	14	10—41 per cent.	24
15 to 20 days.....	36	5—12 per cent.	41
20 to 30 days.....	42	6—12 per cent.	48
30 to 60 days.....	39	2—5 per cent.	41

In patients laboring under certain complications the treatment certainly has little influence on the course of the disease. Those given to the excessive use of alcoholic stimulants have a poor chance for recovery, yet in some of these death appeared to be averted by free stimulation. Those suffering from nephritis nearly all died, and in certain other conditions there were no recoveries, as shown in the following table:

COMPLICATION.	RECOVERED.	DIED.	TOTAL.
Alcoholism	8	31—79 per cent.	39
Nephritis	1	5—83 per cent.	6
Delirium (Marked)...	0	6—100 per cent.	6
Syphilis	0	2—100 per cent.	2
Emphysema	0	2—100 per cent.	2

Remembering how often pneumonia is the cause of suppurative pleurisy it is surprising to note that in these 338 cases only one case is reported to have developed empyema.

THE VARIOUS MEDICAMENTS USED.

Among the various measures often employed in the treatment we notice the use of ice caps, the Leiter coil and cold packs, alcohol rubs for delirium or to reduce temperature, and normal salt solution, given either by hypodermic injection or by enema as a stimulant. Bleeding was employed in only one of the 338 cases. Among the numerous medicines administered certain drugs were employed in large proportions of the cases either alone or combined. They are as follows:

For regulation of the bowels:

Magnesium sulphate was used in 183, or 54 per cent.

Calomel (usually combined with sodium bicarbonate) in 138, or 40 per cent.

For their action on the heart:

Aconite or veratrum viride in 98, or 25 per cent.

Strychnia or nux vomica, or their compounds, in 284, or 84 per cent.

Nitroglycerin or ether in 57, or 17 per cent.

Whisky, brandy, port wine, or spirits of cologne, in 193, or 57 per cent.

Digitalis, spartein, caffeine or strophanthus, in 114, or 33 per cent.

For their action on heart or to relieve cough:

The ammonium compounds in 118, or 34 per cent.

Atropin, hyoscyamus or hyoscin hydrobromate, in 87, or 22 per cent.

For their quieting effects:

Opiates, as codein, morphin, heroin, tr. of opium or Dover's powder, in 170, or 50 per cent.

The bromids of potassium, sodium and ammonium, in 52, or 16 per cent.

Guaiacol carbonate was used in only 19, or 5 per cent.

DISCUSSION OF METHODS.

The reader will naturally ask himself whether better results could have been obtained under other methods, especially under the method that he individually favors, and it is not unlikely that he will usually answer the question in the affirmative and that he may be tempted to criticise the methods of treatment in this institution. It should be recollected, however, that the attending physicians are often unable to carry out their wishes and the hospital authorities are often hampered by patients that they can not control. It is certainly true in this institution that it is impossible to manage the treatment of any class of cases as well as they could be managed in a hospital not entirely under political influence.

The writer, while fully recognizing the impossibility of correcting many of the pathologic conditions that are often found at the autopsy, and although fully aware that the majority of cases of disease recover if left to themselves, is still thoroughly persuaded that much may be done for the alleviation of the suffering and the cure of patients sick with croupous pneumonia. An examination of medical literature shows that many others are of like opinion. The management of patients with pneumonia may be arranged under various heads.

DIET.

Liquid diet should be given regularly and in sufficient quantity, though we need have no fear of the patient starving to death; yet, we must be careful not to overload the stomach and thus add acute indigestion with ptomain poisoning to the burden which the patient is already carrying. As a rule, where it can be borne, half a pint of milk, or its equivalent, should be given to an adult every three hours, and it should not be forgotten that the administration of nourishment every half hour or hour is often injurious; because by so doing the stomach is kept in a constant ferment with no time for rest, so that soon the appetite is lost or nausea and vomiting occur, or the food being passed on to the bowels undergoes decomposition, tympanites results and diarrhea may follow. It is important for the physician to ascertain accurately how much nourishment is being given. It is a common experience to ask the friends or nurses how much food the patient is taking, and to have them answer that he is taking a large quantity, when in reality he is not taking more than a couple of ounces once in three or four hours, or even less frequently. Although there is no danger of starvation, we all know from personal experience how weak one may become by deprivation of one or two of the ordinary meals of the day, and as in pneumonia it is of prime importance to conserve the patient's strength, we should be careful that all of the food is taken that can well be digested. Beef juice, beef tea, mutton broth, clam broth, chicken broth or oyster soup all possess more or less nourishment and any of them may be substituted for milk a part of the time to prevent the patient from becoming tired of the milk. Albumin water, prepared by beating the white of an egg in water, may be used in the same way; barley water or rice water, prepared by boiling these grains for several hours in water until the latter becomes of a milky appearance, and seasoned by lemon juice, if the patient desires, may take the place of a certain quantity of milk. When milk is not di-

gested, as shown by disturbance of the stomach or the collection of gas in the bowels or by the condition of the stools, it should be tried in a partly digested form, and when it is disliked its taste may be altered and the after-taste prevented, at least to a considerable extent, by combining it with Vichy water. Unfortunately in some cases the stomach rejects all food and then it is very difficult to sustain the patient. Under such conditions high rectal enemas should be given three times a day of partly digested and easily assimilable nutriment in quantities of not more than 4 to 6 ounces, and these should not be given oftener than 3 times a day, for if given more frequently the rectum speedily becomes intolerant and they will not be retained.

LAXATIVES.

Many physicians favor beginning the treatment of pneumonia with a mild mercurial purge or a saline laxative; nevertheless, I believe that vigorous catharsis is harmful except in rare instances in very robust persons, although it is desirable that the patient should have one movement a day. In these hospital patients salines were employed in 54 per cent. and mercurials in 40 per cent. of all cases. It has been stated that in this disease the liability to death is in direct relation to the cathartics that have been taken; that is, vigorous catharsis, speedy death.

SURROUNDINGS AND LOCAL TREATMENT.

The patient should, if possible, have a large airy room with free ventilation, but drafts should be avoided and the chest should be carefully protected with a view not only to relieve pain, but to prevent the extension of the disease. It may be urged that we have no means of knowing that the extension of the inflammatory process can be prevented in this way; nevertheless, we do know that the continued application of cold or of hot fomentations will greatly modify the progress of inflammation in other parts of the body, and most of you are familiar with healthy people in whom a reduction in temperature of a few degrees in the surrounding atmosphere will cause much discomfort and pain, and if they do not speedily escape from the condition they are liable to attacks of acute rhinitis, bronchitis or rheumatism; therefore, with a patient depressed by so grave a disease as pneumonia, it seems important to afford extra protection.

The chest may be protected by flannels, by pads of wool or cotton, or the time-honored large jacket poultice enveloping the whole side may be employed if it can be kept constantly warm and can be applied without causing the patient too much discomfort. Poultices that are applied every three or four hours are cold most of the time, and doubtless do more harm than good, and in not a few cases the frequent disturbance of the patient who is in need of absolute rest must have a harmful effect; therefore, these should not be employed excepting in specially favorable cases. Under suitable conditions there can be no question that poultices will frequently greatly diminish the pain, and it is believed by many physicians that they to some extent retard the progress of the disease of the lung. In lieu of poultices many physicians have within the past few years employed soft putty-like preparations, which are spread on the chest to a depth of from $\frac{1}{8}$ to $\frac{1}{4}$ inch and covered with a cloth. These are said to have effects similar to poultices in relieving pain, and it is claimed that they also have some influence in checking the progress of the disease. In the great majority of cases I have found the oiled-silk and cotton jacket much more serviceable than

the poultice or any of its substitutes. This jacket keeps the chest warm and moist, and if properly made it can be easily removed for sponging or for watching the progress of the disease. Such a jacket should be made in two parts, lapping several inches at the shoulders and sides, where it is held together by safety pins. It should have a layer of cheese cloth, which will come next to the skin, just outside of this a layer of oiled silk, the cheese cloth being used to prevent the wrinkling of the oiled silk and the discomfort which this is liable to cause if applied directly to the skin. Outside of the oiled silk should be a layer of cotton batting about two inches in thickness, and outside of this another layer of cheese cloth, the whole being loosely quilted together so that the various parts will keep in their normal position. In these hospital patients the death rate was only 30 per cent. when some such protection was used as against 35 per cent. when nothing of the kind was employed.

In the very early stage leeches or dry cups may be applied to the side for the purpose of relieving pain, and it is probably true that in some cases they limit the extent of the inflammation. Leeches are seldom employed, but dry cups may be easily applied and should be used much more frequently than they are. Counter-irritation by mustard, iodine or blisters has also been highly recommended, but it is doubtful whether it is beneficial except in rare cases. This treatment does not seem to me beneficial during the height of the disease, but in the very beginning, that is, before the physical signs become well pronounced, I believe that it is possible in some cases to abort the disease by counter-irritation, and at the close of the attack I think a similar course of treatment may sometimes hasten resolution.

HEART SEDATIVES.

Believing that pneumonia is a fateful disease that can no more be altered in its course than can typhoid fever, the majority of physicians have entirely abandoned venesection and the use of such heart sedatives as aconite, veratum, tartrate of potash and antimony, iodide of potassium, etc. Nevertheless, cases occasionally occur in robust individuals where the pulse is strong and full, the temperature high and dyspnea developed early, in which some of these agents could be beneficially used for a short time, care always being taken not to greatly deplete the patient and not to exhaust his strength. Such sedatives were given in 25 per cent. of these 338 hospital patients (though probably many of them were treated with very small doses in the homeopathic wards). Such treatment sometimes gives immediate relief, and it possibly renders the course of the disease less severe. During the first 24 hours of an attack of pneumonia ergot has seemed to me to diminish the intensity of the symptoms and to lessen the severity of the attack, but all will be agreed that no depressing agent should be used after the disease is thoroughly established. In those very rare cases where there is undoubted plethora, and when there is great dyspnea with much congestion, the drawing of 6 or 8 ounces of blood from the arm appears to be most beneficial. Bleeding was practiced only once in all of these cases.

PAIN.

To relieve pain the application of heat to the chest, as already recommended, should first be practiced, especially in debilitated patients, but in others better results may be obtained from cold. The latter may be applied by the ice bag or the Leiter coil. The coal-tar antipyretics have also been recommended for this purpose,

and in the beginning of the disease, when the temperature is high and the patient in much discomfort, provided the heart is strong, great relief will often be obtained from the administration of 5 or 10 grains of phenacetin, and I believe it can be given without harm to the patient; however, the dose should not be frequently repeated, and remedies of this class should not be given at all after symptoms of heart failure appear; or, in other words, with a pulse running at about 120. As already suggested, cupping will sometimes relieve this symptom promptly. Physicians too commonly quickly resort to the administration of opiates to relieve this symptom, forgetting that in fully 50 per cent. of the human family opiates disturb the digestion, check the secretions, and within a few hours make the patient worse than he was before; forgetting, also, that opiates benumb the respiratory centers and increase the carbonic acid poisoning, which is so potent for harm in pneumonia; nevertheless, there are some cases in which opiates must be given, but it should be as a last resort and administered with great caution. I am confident that many patients are hurried to the grave by the injudicious use of this agent. Opiates were used in 170, or 50 per cent. of the cases under consideration.

COUGH.

Cough is not infrequently a distressing symptom, especially when the pneumonia is combined with a sharp attack of pleurisy, and something must be given to diminish the convulsive efforts which cause the patient so much pain and which undoubtedly increase the congestion of the lungs. For this purpose ammonium bromid in doses of 10 grains every 2 to 6 hours combined with hyoscyamus in moderate doses has been the most satisfactory in my hands, but here again we will sometimes have to resort to opiates, and when we do that preparation that is least likely to disturb the digestion or to give the patient discomfort should be employed: I like codein best. Atropin or hyoscyamus was used in 22 per cent. of these hospital cases.

INSOMNIA.

Sleeplessness is one of the most distressing symptoms in this disease, and not infrequently patients go for two or three days, or even longer, with not more than a few minutes' sleep at any time. As a result they become greatly exhausted and much less able to withstand the ravages of the disease. It therefore becomes important to relieve this symptom. The bromid of ammonium already recommended for relieving the cough tends also to prevent insomnia, or if the latter is the prominent symptom it may often be cured by this drug. The hospital records show that bromids were used in 16 per cent. of the 338 cases. Sulphonal, trional, chloral, chloralose and chlorotone have all been recommended for the same purpose, but chloralamid, which has the reputation of being a heart stimulant, theoretically appears especially adapted to this end, and practically it will sometimes be found most beneficial, though there are some patients in whom it has an unpleasant action. Here, too, opiates are recommended and employed by many physicians, but the treatment appears to me most injudicious. Full doses of whisky sometimes produced the happiest effects in securing sleep for these patients.

TEMPERATURE.

The two prominent indications in the treatment of pneumonia are acknowledged by nearly all physicians to be reduction of high temperature and sustaining the heart. A temperature below 102 is not generally considered injurious and no special efforts are made to re-

duce it, but when it goes beyond this it is a common practice to have the patient sponged, with a hope of reducing the heat one or two degrees; this treatment is repeated every three or four hours as necessary. Sometimes the tub bath, cold packs, or even hot packs, are used for the same purpose, and ice bags or the Leiter coil may be applied over the abdomen or over the affected portion of the chest with the result of quickly bringing down the temperature. Any of these methods under proper conditions and in suitable cases may be employed with apparent benefit. These methods are commonly employed in Cook County Hospital practice. Guaiacol in the quantity of from 20 to 30 minims may be rubbed into the skin, either directly over the affected lung or in other parts of the body, with the effect of speedily reducing the temperature one or two degrees and often of exciting profuse diaphoresis. Although there is some fear of its depressing effects on the heart, there is little danger in this direction if it is employed in suitable quantities. Theoretically, whatever part of it is absorbed should act beneficially on the lung, possibly in diminishing the propagation of the pneumococci and thus lessening the amount of their toxins, and practically it has appeared to act beneficially in many cases. The various coal-tar derivatives have also been used for reducing the temperature, and so long as the symptoms are mild they may probably be employed in small and infrequent doses without detriment to the patient; but with a pulse above 110 they should be used, if at all, with the greatest circumspection; indeed, I think few physicians would at this day recommend them. The alkaline diuretics and diaphoretics, for example, the acetate of potassium and liquor ammonium acetatis, undoubtedly aid in keeping down the temperature, and there is some reason for believing that they may, to a slight extent at least, retard the croupous deposit in the lung or aid in its absorption.

SPECIFICS.

Are there any remedies which possess a specific influence for the cure of croupous pneumonia? I fear not; yet, the remarkable effects claimed for creasote, carbolic acid and the salicylates of sodium and ammonium, and even for chloroform, and the reliance placed on this class of remedies by Andrew H. Smith, would seem to indicate that they possess a power over pneumonia similar to that of quinin over malarial fever and of the salicylates over acute rheumatic fever. From the various facts and opinions collected Smith is induced to say (20th Century Practice of Medicine, Vol. 16, page 99): "We may reasonably expect benefit in a considerable proportion of cases from the use of means addressed directly to the germ present in the lungs. The practical question to be solved is, what agent will act most powerfully on the specific organism with least inconvenience or danger to the patient? . . . Thus far the most efficient and least harmful drug appears to be the salicylate of sodium, as employed by Liegel. As we have seen 72 consecutive cases, many of them most unpromising, have been treated with it without a death. This is a very remarkable record and certainly recommends the treatment most strongly for further trial. Apart from the experience of Liegel, it does not appear unlikely that a drug which is capable of producing such decided results in acute rheumatism should be effective against an organism so sensitive as the pneumococcus. Liegel did not observe any depressing effect from the salicylate of sodium in the doses he employed (8 grams daily), but such if apprehended could be guarded against by the use of strychnin, etc.

CREASOTE.

Creasote has been found useful by several observers and deserves further trial. It may be given by the mouth or rectum or employed by inhalation. The dose by the mouth is 10 to 15 minims every two or three hours, largely diluted; by the rectum, 25 to 40 minims in a clyster. By inhalation it is useful only as an adjunct." A. H. Kerr¹ says: "I do not say that creasote is a specific for pneumonia, but I do say, with emphasis, that it is the nearest approach to one that has yet been reached." Beverly Robinson² strongly insists on the value of creasote inhalations from the very beginning of an attack of pneumonia, not only for their beneficial effects on the patient, but as having a tendency to lessen the danger of infection to the attendant. He says: "If we may attach faith to the experimental researches of Welch . . . the *Micrococcus lanceolatus* the admitted cause of croupous pneumonia, is a pathogenic organism, one of those least tenacious of life and . . . its loss of virulence is frequent and apt to occur rapidly. Is there not in this important fact a very substantial reason why we should endeavor to employ antiseptic inhalations early in the treatment of pneumonia, before lung consolidation has taken place, and while we may yet legitimately hope that the antiseptic vapor may reach every portion of the affected pulmonary area?"

SALICYLATES.

Robert Liegel,³ in describing 72 consecutive cases of pneumonia occurring in the miners of Leoben See-graben, all of whom recovered, states that 8 of these had pulmonary emphysema, 6 cardiac disease and a large proportion were alcoholics and that no other medicine than the sodium salicylate was employed, excepting, perhaps, an expectorant containing ipecac if the cough was tight and hacking, and small doses of morphin when the pain was excessive; ice was used to the head when the temperature ran above 103 degrees F. As already stated, 79 per cent. of the alcoholic and all of the emphysematous were fatal in our hospital cases. He claims that the disease was not more than one-half the usual duration, but that crisis did not occur in any case, the temperature gradually declining from the end of the first day until the third or fourth day, when convalescence was established. Microscopic examinations of the sputa showed a constantly diminishing number of diplococci until they were found to have entirely disappeared with the beginning of convalescence. He found that when the medicine was discontinued as soon as the temperature became normal relapses were liable to occur, therefore he recommended that it be continued for two or three days longer. He considers that the salicylates exert a specific effect such as that which they exhibit in rheumatic fever, and he believes that if used in this way they would save nearly all cases. He said that the remedy caused no unpleasant symptom excepting buzzing in the ears. These remedies have not found favor with the attending physicians in the hospital, although guaiacol carbonate was used in 5 per cent. of the cases. Wm. C. Sebring⁴ reports 75 cases treated with two drams of the salicylate of sodium daily with one death, and J. H. Ferguson is recorded by Smith⁵ as having treated 106 cases of pneumonia with sodium salicylate with only 6 deaths, but he gave only 60 grains daily and administered it in combination with the citrate of potassium. Others report similar results almost as favorable from the salicylate of sodium or the salicylate of ammonium. The latter would seem to have some advantages, although it

appears not to be quite as well borne by the stomach.

CARBOLIC ACID AND GUAIACOL.

Carbolic acid has also been recommended in large doses. Arthur Wigglesworth,⁶ speaking of the treatment of scarlet fever, states that he has given as much as 6 grains every 2 hours day and night, and A. H. Smith says that he has given as much as 150 minims of the liquefied acid in 24 hours for several days without unpleasant results.

If creasote and carbolic acid can be used in such quantities there seems to be no reason why guaiacol might not be used much more freely and continuously than I have thought judicious. It possesses the advantages of acting quickly and reducing the temperature and of being readily absorbed by the skin so that it does not need to be given internally. Judging from the quantities of the salicylates, carbolic acid and creasote that have been given with impunity it would appear that about half a dram of guaiacol might be rubbed on the surface every two to four hours, and I can see no objection to instituting this treatment so long as its effects are carefully watched and the temperature is not reduced too low. It usually produces free sweating within half an hour after its application, which would be desirable if not carried too far.

CHLOROFORM.

According to Andrew H. Smith, Baumgartner Wucherer and Thiel employed inhalations of chloroform or ether for the treatment of pneumonia. Clemens⁷ gave inhalations of chloroform to relieve the pain and shortness of breath, belonging to the early stages of pneumonia, as early as 1850, and continued it throughout the remainder of his practice without losing a single case. He stated that it often hastened the crisis and that it lessened the average duration of the disease. Oertel⁸ reported decided benefits from the inhalation of chloroform, which he employed mainly in the advanced stages of the disease, about the fifth or sixth day, when there was extensive hepatization with pleuritis which rendered the breathing irregular, frequent and superficial and when the expectoration was scanty and viscid and there were coarse râles over a large area of the lungs with rapidly increasing cyanosis. These inhalations were repeated as often as 5 or 6 times a day and pushed to commencing narcosis with most satisfactory results. The respirations became deeper, the pain was relieved, the râles were diminished, expectoration increased, cyanosis became less marked and general betterment ensued. Oertel sums up his experience in the following way: "I consider the inhalation of chloroform when the above indications are present as a means of treatment in pneumonia that would be difficult to replace by any other." However, he did not favor it when the patient suffered much from headaches, vertigo or mental confusion with involvement of both lungs or with general depression. Smith suggests that the penetration of chloroform to all parts of the lung and its diffusion throughout the entire system in these cases renders the exudate in the air cells an unfit medium for the culture of the pneumococcus and thus lessens the production of the toxin. He says, further: "Aside from any action upon the germs the chloroform will aid pain, soothe nervous agitation and promote sleep." He suggests giving it in connection with oxygen by adding one or two drams to the water in the wash bottle, but says that if the abortive action is aimed at it must be given in more concentrated vapor.

HEART STIMULANTS.

In the severe or exceedingly grave cases it becomes

of the greatest importance to support the heart, and with this end in view remedies classified as heart tonics and stimulants are commonly employed. Of these there is none of more value than *nux vomica* or its derivatives. When we have a preparation on which we can rely, I believe that we get more satisfactory results from the tincture of *nux vomica* or the fluid extract than we do from strychnin or any of the other derivatives of this drug, but unfortunately these preparations vary much in strength; they should be given in small but steadily increasing doses and frequently repeated until we obtain their physiologic effects on the heart and respiratory centers. The tincture of *nux vomica* may be given in doses of from 10 to 20 or even 30 minims every 2 to 4 hours, in severe or very grave cases, or strychnin may be given in doses of from 1/60 to 1/40, 1/30, or even 1/20 of a grain under similar conditions. These were given in 84 per cent. of these hospital cases. There is no danger so long as the patient is watched and the dose diminished with the development of its toxic symptoms. It should be remembered, however, that in young children convulsions frequently occur in pneumonia, and therefore with these the remedy should be used more carefully, not only for its effect on the patient, but also that the friends may not attribute a convulsion to the medicine. Digitalis and other so-called heart tonics have also been highly recommended in this condition, but they have appeared to me of little or no benefit, indeed, in acute inflammatory affections of the myocardium or in the acute weakening of the heart resulting from any of the infectious diseases or septic conditions, I have yet to see a single case in which digitalis or its congeners appeared to me to be beneficial; on the contrary, it has seemed to me that they often do actual harm. I am aware that this is not in accord with the belief of the majority of the profession, and that many authorities have the greatest confidence in this drug; for example, Petresco highly extols enormous doses of digitalis, giving from 75 to 150 grains of the powdered leaves daily, and he reports that out of many hundred cases among soldiers he has had a death rate of only 1.2 to 2 per cent. with the crisis commonly occurring on the third day. Other authors report favorable results from large doses, but still others who have experimented with it have felt compelled to abandon its use on account of its toxic effects. Usually, however, the remedy is not employed in these heroic doses, but rather in the quantities that we would use in severe cases of chronic cardiac disease. Remedies of this class were used in 33 per cent. of our cases.

SALT.

When the secretions are checked and the skin hard and dry, with the tongue dry and brown, the pulse weak and rapid and the respiration shallow and quick and subsultus indicates depression, great benefit may sometimes be obtained from the administration by hypodermoclysis or high rectal enemas of half a pint to a pint of decinormal salt solution; or better, the normal salt solution to which has been added a small quantity of a calcium salt. Ringer's solution may be employed for the purpose. It consists of a 1 per cent. solution of calcium chlorid 3 parts, a 1 per cent. solution of potassium chlorid 4 parts, a 1 per cent. solution of sodium chlorid 70 parts and distilled water 23 parts. Prof. Jacques Loeb's experiments have shown that the turtle's heart may be made to beat for hours or days in a solution of chlorid of sodium, but that no solution other than the sodium salts or of sugar can be substituted without stopping the pulsations. His and other

experiments have also shown that the turtle's heart which has ceased to beat after a few hours' immersion in a normal salt solution may be speedily revived by the addition of a small amount of the salts of calcium or of some of the other bivalent metals, such as strontium, and may then go on beating for 20 to 24 hours. This would indicate that a very small quantity of the calcium salt should always be added to the normal salt solution in order to obtain its best results. Loeb recommends especially 1 per cent. of a saturated solution of the sulphate of calcium with 99 per cent. of the normal salt solution. The chlorid of calcium may, however, be used instead of the sulphate in the proportion of one part of a 2 per cent. solution to 99 parts of the normal salt solution, which would equal nearly half a grain to the ounce. He urges, however, that it is best to use the sulphate of calcium, which is only sparingly soluble in water and which may therefore be used without possible error. Too much of the calcium is quite as deleterious as too little. The effect of administration of the salt solution is often shown in a short time by change in the condition of the tongue, by the increased excretion of urine and by general betterment of the patient's condition.

ALCOHOLIC STIMULANTS.

Not a few physicians begin the use of alcoholic stimulants early and continue them in large quantities throughout the course of the disease, but this practice has never seemed to me judicious, though I confess that their patients not infrequently recover in spite of the treatment. In severe or very grave cases, with the pulse above 135 and the respiration above 45, with symptoms and signs indicative of the beginning of pulmonary edema, free stimulation is often followed by most gratifying results. The dose of alcohol that should be used can not be definitely stated, but it must be graduated for each individual patient according to its effect on the heart and respiration. If, under its influence, the heart's action grows stronger and the respirations less frequent, and if the patient's general condition appears to be improved, and if he is enabled to sleep, we may continue its use and gradually increase its quantity according to its effect. From 16 to 24, or even 36, ounces of good whisky in 24 hours is not excessive in many of these cases, but when this quantity becomes unnecessary the patient will begin to experience head symptoms, and then it should be diminished. I have seen the most gratifying results follow its use in many very grave cases by sustaining the patient for 12 to 24 hours during the most critical stage of the disease, and I have seen some patients where it had to be employed in large doses for three or four days. Whenever a patient has been previously addicted to the use of alcoholic stimulants, it is generally recognized that they should be given early and continued freely. Alcoholic stimulants were employed in 57 per cent. of these hospital cases, though seldom in large quantity.

DYSPNEA.

When dyspnea becomes marked and the lividity of the nails shows that the blood is imperfectly aerated, the same remedies are indicated that were recommended for heart failure, but the chief among these are *nux vomica* or its derivatives and alcoholic stimulants. The most logical remedy for this particular symptom is oxygen, which will sometimes carry the patient through the critical period and save life, but usually its effects are not very apparent, for the reason that it is not given until too late, or that it is not given in sufficient quantity. In order to obtain the best results from this agent it

should be given early and frequently or continuously and in as large quantity as may appear to be beneficial to the patient; but it is not well to annoy patients by forcing it on them. The inhalation can usually be administered without annoyance by placing the funnel within a short distance of the patient's mouth, though if it does not worry the patient the inhaler should be applied closely. It is desirable to begin the use of this agent as soon as dyspnea is distinct. There is no danger in giving it continuously if it appears to be benefiting the patient, though it is generally administered for only 5 or 10 minutes at a time every half hour or hour, or less frequently, according to the amount of dyspnea and the lividity that is apparent. Loeb says the most important factor in the pulsations of the heart is the presence of oxygen, as illustrated by the fact that the pulsations of a turtle's heart in a salt solution may be prolonged for several days by passing a current of oxygen through the solution.

SERUM TREATMENT.

The experiments of G. and F. Klemperer on the curative effects of the blood serum of immune animals are extremely interesting and have shown that other animals may thus be rendered immune to the effects of the *Diplococcus lanceolatus*; but the use of this serum on human beings has not been followed by uniformly favorable results; indeed, in the majority of cases it has appeared to be innocuous, although many cases all told have been reported in which patients have done well while it was being administered. In estimating its value the natural history and tendency of the disease must always be taken into consideration, and the fact that a crisis occurs within a few hours after the administration of a dose of the antipneumotoxin can not be considered as positive proof that the remedy had any effect in producing the crisis. It is only when such results have been obtained quite uniformly under a large number of experiments that certainty can be acquired. Several attempts have been made to test the value of this treatment in the hospital, but for various reasons the trials have not been extensive. So far as any deductions can be drawn, the results have been negative.

CONVALESCENCE.

During convalescence from pneumonia the patient should be careful to avoid all undue exposure or exertion, for it is a recognized fact that there is considerable danger of recurrence within six months. The weakness of the heart also is likely to demand moderation in exercise and the local condition of the lung as well as the patient's general condition requires the avoidance of exposure. In those cases where the consolidation does not speedily resolve I believe that the progress can be stimulated by the administration of the chlorid of calcium, the iodid of ammonium and possibly by alkaline diuretics such as the acetate of potassium. Such patients usually need also bitter and sometimes ferruginous tonics, and unless convalescence is established within 6 or 8 weeks it is desirable that they be sent to a dry climate at a moderately high elevation, though in this the condition of the heart should always be considered. Late in the disease counter-irritation is sometimes recommended, but it is of doubtful utility.

DISCUSSION.

DR. J. R. BARNETT, Neenah, Wis.—I was disappointed that the Doctor did not allude to puncture of the lung—in cases of delayed resolution in pneumonitis. A short time ago a physician of Chicago reported the results of puncture in such cases. I regret that I can not give his name, and accord due credit to the first published report of what I regard as a most valuable procedure.

Something like eight years ago, in mistaking delayed resolution for a pleurisy, I aspirated the pleural cavity but, of course, found no fluid. I then carried the needle into the lung, which resulted in the clearing up of the exudation and a rapid recovery. A year ago a similar condition presented in a child of 5 or 6. At the end of six weeks there was skin fever, and the dulness—almost flatness—occupied nearly the entire lung. The other also was a little involved. In this case, as in the others, the apex of the heart was displaced. Aspiration showed no pleural fluid and the lung was punctured deeply in two places, in the seventh and eighth interspaces. Recovery was prompt and complete. A few weeks ago I made use of this procedure in the case of a woman. The lung had remained solid for one month, with a continuous temperature, and her condition was so grave that recovery was thought to be impossible. About two ounces of blood escaped through the canula. She is rapidly improving. I have used salicylate of ammonium in pneumonia with the greatest satisfaction during the past twelve years. Up to the stage of commencing resolution I think it can be used with much benefit. We in the country have no such mortality percentage as the hospitals report. Personal conditions and environment are better.

DR. H. A. WEST, Galveston, Tex.—I wish to make a few remarks with regard to the use of the coal-tar antipyretics in pneumonitis such as we see in Texas. During the past winter I watched a type of pneumonia that was prevalent in different portions of the state of Texas which was attended with great mortality. I have seen doses of seven grains of phenacetin, given for the reduction of temperature, produce serious collapse. In all diseases like pneumonia where the tendency to death is from cardiac depression, the coal-tar antipyretics or any other depressant agents are, in my opinion, absolutely contraindicated. It is not contended—so far as I know—that remedies of this coal-tar series produce any other than a mere palliative effect. They neither shorten the duration of the disease or obviate a fatal result, but, on the contrary, may directly contribute to that end. Hence my absolute and unqualified protest against the use of these remedies in pneumonia.

DR. WILLIAM OSLER, Baltimore—I did not propose to enter into the discussion of the treatment of pneumonia—the session is too short—but I rise to make an appeal. We have had presented a statement which should impress all of us as appalling. When we think that other infectious diseases we treat have had their mortality reduced some 10 or 15 per cent. it is terrible to realize that we, as physicians, must listen with mute impassive faces to the announcement of a 36 per cent. mortality in pneumonia. It is an old story, one to which we have been listening to for years and years. You will find that in private practice, in hospitals, in jails, in barracks, in the field and in the camp, the mortality has been always about 25 per cent. What I feel deeply is that something should be done, in a systematic and energetic way, to study this problem of pneumonia and to see if we can not reduce this death rate of 36 per cent.! Gentlemen, this mortality is dreadful, and if it occurred in typhoid fever it would be considered appalling. This record—by no means an uncommon one—should stir us up to do something energetic. I should like to ask the hospital physicians to pay more attention to the specific study of these cases, to study carefully the methods of treatment, and to see if we can not devise some way to reduce this high mortality. We do not give enough attention to the study of pneumonia; many look at it in a helpless sort of way; our best knowledge

should come from general practitioners who study the disease in an intelligent and proper manner. I am sorry Dr. Ingals did not tell us of the mortality on the homeopathic side of the Cook County Hospital—whether it was lower than the mortality on the side of the regular practitioners. Homeopathy taught us a good lesson in the treatment of pneumonia; it led to the abandonment of bleeding, sweating, the use of tartar emetic and other depressing agents.

DR. WILLIAM BAILEY, Louisville, Ky.—I regard the paper an able and efficient one. As a general practitioner for more than forty years and as one who believes this to be a self-limited disease, I am convinced that much can be done for the benefit of the patient the subject of pneumonia and, in the early stages, much can be done to limit the disease. I do not agree with Dr. West that it is unsafe to reduce the temperature with some of the coal-tar derivatives. During the first day or two of the disease I do not think that I make a mistake in using some of them for this purpose. The use of phenacetin, with quinin, supported by citrate of caffein, reduces the temperature safely, promotes comfort and limits the amount of tissue involved. I am sure that much can be done for the comfort of the patient in this way. I also believe that some form of opium can be given with advantage; small doses of Dover's powder will lessen the cough and relieve the distress of the patient, as will codein or heroin. The personal equation and the powers of resistance of our patients should be always considered. Death in pneumonia is by asthenia and so the heart of the patient should be supported by the use of strychnin and digitalis. If there is much tissue involved and death is threatened by apnea then oxygen will sometimes save lives.

DR. E. F. WELLS, Chicago—In making a statistical inquiry into the mortality of pneumonia, in connection with a paper which I to-day presented to another Section of this Association, it appears that, among a very large number of cases, extending over a long period of time, the death-rate has remained practically the same, no matter where it occurred, or how treated. It is, therefore, my opinion that the death rate is now no greater, no less, than formerly. I wish to call attention to one point in the symptomatology of pneumonia; it begins with extreme suddenness, and changes for the worse or for the better occur suddenly. If then, with our present knowledge and resources, we desire to reduce our mortality in pneumonia, we must be prepared to meet promptly these unexpected and dangerous emergencies as they arise. In this connection I wish to make a plea for a more careful and constant attention to these cases, for I am satisfied that I have, in some cases, seen lives saved by the physician being in constant attendance on them.

DR. JAMES J. WALSH, New York—I have just taken part in the discussion on the prevalence and fatality of pneumonia in the Section on Hygiene and Sanitary Science. From the communications made there and the present discussion there can be no doubt that while the disease is increasing in frequency the percentage of mortality from it is at least as great as it was 75 years ago when statistics on the subject were first collected. The question of prevention becomes an extremely important one, then, and precautions that would seem to be exaggerated will have to be considered to prevent the spread of the disease. The sputum of pneumonia patients probably contains infectious elements and will have to be taken care of as conscientiously as tuberculous sputum. Twenty-five years ago the suggestion that tuberculous sputum carried infection would have been laughed at. It seems not unlikely that a similar change of opinion will take place with regard to the sputa of pneumonia patients. The denser the population the greater the frequency of pneumonia and also the higher percentage of mortality. Life in crowded centers is becoming more common and the pneumonia problem is constantly becoming more serious. The question of dust and its dangers, especially in such places as churches, theaters, railway stations, etc., will have to be taken under consideration by city boards of health if the prophylaxis of pneumonia is to be seriously attempted.

DR. R. M. CUNNINGHAM, Ensley, Ala.—I can not allow the

present opportunity to pass without adding a few remarks to the discussion of this subject. During the last twenty years I have observed in the prisons of Alabama more than 600 cases of croupous pneumonia. These cases occurred mostly in epidemics, from 20 to 90 odd cases in each. Most of these cases were in the prisons where convicts work, in coal mines, but there were as many cases in proportion among those at these prisons who were employed on the outside as among those who were employed on the inside of the mines. Hence, if there was any special causative factor at work, it was in the prison and not in the mines. Nearly all these were negroes; there was a much smaller percentage of the white convicts attacked. The hygienic conditions of these persons were good. The epidemics would come and go without apparent cause or reason, the hygienic conditions, clothing, food, work, etc., remaining the same. Some of the worst of these epidemics have been in the late spring and summer, the worst, so far as mortality is concerned, being in July and August. Sporadic cases have been rare. A singular feature has been the large number of the able-bodied men attacked. Another feature was—in some of the epidemics—the small number of cases among the convicts who worked in the mines at night, but who slept in the prisons in the daytime. The mortality rate has varied from 10 to 60 per cent. The average for the 20 years has been about 30 per cent. The difference in the mortality has been due to the type of the disease, notably in the severity of the toxemia, the extent of the pulmonary area involved, and the tendency to complications—meningitis, pericarditis, etc. Considering that these cases occurred in negro convicts, subject to the environment of prison life, the severity of the cases, the large area of lung tissue involved, etc., I think the death rate is fair. I am persuaded, therefore, that there is something in the treatment of croupous pneumonia. There is no specific, no universal treatment. Each case, modified by the type of the epidemic, is a law unto itself. The range of this treatment is from the most pronounced antiphlogistic to the most thorough stimulant, each case determining what is best. The best antipyretic is the cold bath; the next, 20 to 30 grains of quinin. The tar derivatives have no place in the treatment of the disease. I am sure they were the cause of death in several cases where they were employed. They reduce temperature promptly, but at the expense of a cardiac power. Strychnin, whisky and digitalis, in the order named, are the best stimulants—the one to be selected most adapted to the particular case. Hypodermoclysis of normal salt solution I have seen save life. This is the chief reliance in those cases ushered in with profound shock. Salt solution also, in a great measure, prevents heart clots. I am of the opinion that these thrombi are often antemortem, and often the immediate cause of death. To prevent them is one of the objects of treatment. I am of the opinion that our best means to do this is salt solution. We should never give up a case of croupous pneumonia until the death of the patient. The most remarkable results sometimes follow the right treatment at the right time.

DR. F. D. REESE, Cortland, N. Y.—In the treatment of pneumonia there are three objects to be attained: to open the bowels, the kidneys and the skin. I give calomel to open the bowels, acetic acid and carbonate of ammonia to open the skin and reduce the temperature, and acetate of potassium to open the kidneys. The heart should be supported with an appropriate stimulant. I also order the cotton jacket. Of my last ten cases all have recovered under this treatment except one.

Another "Singular Coincidence" Among Dentists.—In looking over the last issue of the *Dental Review*, says the *Dental Digest*, we notice the president's address, delivered before the Indiana State Dental Association, in June of this year, by Dr. C. E. Pittman. The address is two pages long, and one page of it is identical in wording with the president's address delivered before the Illinois State Dental Society, by Dr. J. G. Reid, in May, 1901, and printed in the *Digest* for July, 1901. Great minds move in the same channel.

THE PRESENT ASPECT OF THE TUBERCULOSIS PROBLEM IN THE UNITED STATES.*

S. A. KNOFF, M.D.
NEW YORK CITY.

Five years ago, on the fiftieth anniversary of our beloved Association, it was my privilege to read before this Section a paper with the title "The Present Status of Preventive Means Against the Spread of Tuberculosis in the Various States of the Union Critically Reviewed." To-day I shall endeavor to present to you as precise a report as possible of what has been done by the same states during the past years, and give you a bird's-eye view of the present aspect of the tuberculosis problem in the United States. I am indebted for my information to the courtesy of the presidents and secretaries of the state boards of health and a number of health officers of cities.

REPORTS FROM THE VARIOUS STATES.

The following are the questions which were sent out, and to which 48 state boards, 2 territorial and 25 city boards of health have replied:

1. What laws or regulations exist in your state (city) to combat the spread of tuberculosis (pulmonary or other)?
2. What recommendations, ordinances, circulars, public notices, etc., has your honorable board issued with the same purpose in view?
3. What sanatoria, special hospitals and dispensaries for the exclusive treatment of tuberculosis, private or public, for adults or children, exist in your state (city)?
4. Has your state or any city in your state a society for the prevention of tuberculosis?
5. What measures, laws or regulations exist in your state (city) to combat bovine tuberculosis?

ALABAMA: No laws or regulations concerning tuberculosis in man; no ordinances or circulars; no sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis; no bovine laws. Reported by W. H. Sanders, M.D., State Health Officer.

ARIZONA: No board of health; no laws or regulations concerning tuberculosis in man; no circulars, etc.; no sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis. Most stringent and rigid laws concerning tuberculosis in cattle exist and are well enforced. Reported by Wm. Duffield, M.D., Health Officer.

ARKANSAS: No laws or regulations concerning tuberculosis in man; no ordinances or circulars; no sanatoria, special hospitals, or special dispensaries; no society for the prevention of tuberculosis; no bovine laws. Reported by R. B. Christian, M.D., Secretary State Board of Health.

CALIFORNIA: No laws or regulations concerning tuberculosis in man; no recommendations, except those appertaining to general contagious diseases. One private institution, "Idylwild Sanatorium," in Southern California, Dr. Walter Lindley, Los Angeles, Director. No society for the prevention of tuberculosis. Some local ordinances requiring dairy cows to be submitted to the tuberculin test. Reported by W. P. Matthews, M.D., Secretary State Board of Health.

COLORADO: No laws or regulations concerning tuberculosis in man, except anti-spitting ordinances. A good circular to combat the propagation of tuberculosis in man is issued. There exist the "Protestant Episcopal Home" for pay patients only; "The National Jewish Consumptives' Hospital," under the control of the "Bnai-Brith," a national Jewish benevolent society; this institution cares only for charity patients; the "Glockner Sanatorium," at Colorado Springs, in charge of the Sisters of Charity, for pay patients; another sanatorium is projected under the direction of Dr. S. E. Solly; "The Rocky Mountain Sanatorium," in course of construction, for pay and charity patients, in charge of Dr. A. M. Holmes. There is a

Society for the Study and Control of Tuberculosis; president, Dr. Wm. P. Munn; secretary, Dr. G. E. Tyler. No special bovine laws; local boards of health have the authority to order the destruction of any animal that is affected with the disease. Reported by G. E. Tyler, M.D., Secretary State Board of Health.

CONNECTICUT: No laws or regulations concerning tuberculosis in man. A good circular is issued for public information, entitled "Consumption, Its Cause and Means of Prevention." No sanatoria, special hospitals or special dispensaries at present, but \$25,000 were appropriated to the Hartford Hospital to establish and conduct an experimental hospital for consumption. No society for the prevention of tuberculosis. There have been some laws to combat bovine tuberculosis, but they have been repealed. Reported by Prof. C. A. Lindsley, M.D., Secretary State Board of Health.

DELAWARE: No answer has been received. Through the courtesy of Dr. W. A. Evans, Chicago, I learned that there are enactments bearing on the subject of tuberculin; no further details were furnished.

DISTRICT OF COLUMBIA: It is unlawful to expectorate in public vehicles or in buildings under control of government. Physicians reporting deaths from tuberculosis are notified to have the premises disinfected. A circular of information has been prepared for physicians of the poor, dispensaries, etc. No sanatorium, special hospital or special dispensary; no society for the prevention of tuberculosis; no bovine laws. Reported by Wm. C. Woodward, M.D., Health Officer.

FLORIDA: No laws, except that some cities have anti-spitting ordinances. The state board has issued publications containing general advice concerning disinfection and disposition of sputum. A special institution for tuberculous patients was started at Orlando, but has now become a general hospital. No society for the prevention of tuberculosis; no bovine laws. Reported by Joseph Y. Porter, M.D., State Health Officer.

GEORGIA: No answer has been received. Through the courtesy of Dr. W. A. Evans, Chicago, I learned that there are no laws relating to tuberculosis in man or beast.

HAWAII: The Territorial Board of Health has no laws regarding tuberculosis in man, but has issued anti-spitting regulations and some good instructive leaflets for consumptives. Physicians are required to report cases of all forms of tuberculosis. No sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis. There are no bovine laws, but some bovine regulations. Reported by J. S. B. Pratt, M.D., executive officer.

IDAHO: No state board of health. Dr. E. L. Nourse, Secretary of the State Board of Medical Examiners, reports that there are no laws concerning the question of tuberculosis or other infectious diseases, except such as each town may individually make for its own protection. Tuberculosis is rare, consequently there are no institutions for the treatment and no societies for the prevention of the disease.

ILLINOIS: No laws or regulations concerning tuberculosis in man. No ordinances or circulars. Chicago Sanatorium for Tuberculosis, Dr. J. A. Robison, Director; Cook County Hospital; Illinois Society for the Prevention of Tuberculosis, president, John McLaren; secretary, Dr. J. A. Robison. Bovine laws formerly enacted and executed by the Live Stock Commissioners are no longer enforced for lack of appropriation. Reported by J. A. Egan, M.D., Secretary State Board of Health.

INDIANA: No laws or regulations concerning tuberculosis in man. Physicians are requested to report cases so that health boards may send circulars containing excellent instructions for the prevention of tuberculosis. One private institution in Indianapolis and another in New Albany. No society for the prevention of tuberculosis as yet, but there is agitation for its formation. No bovine laws. Reported by J. N. Hurty, M.D., Secretary State Board of Health.

INDIAN TERRITORY: The secretaries of the Cherokee National Board of Health and of that of the Choctaw Nation replied negatively to all questions.

IOWA: No laws or regulations concerning tuberculosis in man. Circulars and a bulletin are issued instructing the people in the methods of the prevention of tuberculosis. A private sanatorium is in operation at Fort Dodge under the direction

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee: Drs. Arthur R. Reynolds, George Cook and Heman Spalding.

of Dr. J. W. Kime. No society for the prevention of tuberculosis; no bovine laws. Reported by J. F. Kennedy, M.D., Secretary State Board of Health.

KANSAS: No laws or regulations concerning tuberculosis in man. Reporting for the purpose of disinfecting premises at frequent intervals and after the disease has run its course has been recommended to the board of health. No sanatorium, special hospital, or special dispensary; no association for the prevention of tuberculosis. No specific bovine laws, but the sale of diseased animals is punishable by fine or imprisonment. Reported by W. B. Swan, M.D., Secretary State Board of Health.

KENTUCKY: No specific laws or regulations, but claims wide authority of general sanitary laws. A good circular is issued on the prevention of consumption. No sanatorium, special hospital or special dispensary; no society for the prevention of tuberculosis; no specific bovine laws, only those appertaining to the spread of contagious diseases in animals. Reported by J. M. McCormack, M.D., Secretary State Board of Health.

LOUISIANA: No laws or regulations concerning tuberculosis in man. The only circular issued appertains to the gathering of statistics. One private sanatorium directed by Dr. G. R. Tolsen, at Covington. Committee appointed to urge the advisability of establishing a state sanatorium. No society for the prevention of tuberculosis. No compulsory bovine laws, but tuberculin test is offered gratuitously by New Orleans City Board of Health. Reported by G. Farrer Patton, M.D., Secretary State Board of Health.

MAINE: The law makes it a duty of householders and attending physicians to report cases of pulmonary tuberculosis to the local boards of health; the latter in turn must report to the state board. Disinfecting of premises is recommended to householders who own their own homes; compulsory if the death occurs in a rented house or apartment. Excellent circulars for the prevention of consumption and for the disinfection of rooms and things used by consumptives are issued and widely distributed. *The Sanitary Inspector*, a journal devoted to personal and public hygiene, has issued 9,000 copies of an admirable special tuberculosis number; it is edited by Dr. A. G. Young. No sanatoria, special hospitals, or special dispensaries. There is a Maine State Sanatorium Association, of which the governor is president and Dr. A. G. Young secretary. There are good bovine laws which become most effective through the combined action of local boards of health and cattle commissioners. Reported by A. G. Young, M.D., Secretary State Board of Health.

MARYLAND: No special laws, but a bill is pending to create a tuberculosis commission. Many pamphlets and instructive circulars are issued. The Maryland Hospital for Consumptives; the Laennec Society for the Prevention and Study of Tuberculosis of Johns Hopkins. The Maryland Public Health Association has devoted much attention to tuberculosis. State Live Stock Sanitary Board has control of dairies. State Board of Health confiscates and destroys tuberculous animals at abattoirs and stock yards. Reported by John S. Fulton, M.D., Secretary State Board of Health.

MASSACHUSETTS: No special laws relating to tuberculosis. Excellent circulars on the prevention of tuberculosis are widely circulated. Bacteriologic examination of sputum is made gratuitously. State Sanatorium at Rutland; Cullis Home for Consumptives, Boston; Free Home for Consumptives, Boston; Sharon Sanatorium, Sharon; private sanatorium of Dr. Millett, Brockton. No society for the prevention of tuberculosis. Cattle commission has control of bovine laws, acting under the Board of Agriculture. Reported by Samuel W. Abbott, M.D., Secretary State Board of Health.

According to the *Medical News*, of Dec. 7, 1901, there exists near Plymouth an open-air colony for consumptives. There the patients live in shacks about 12 feet square, of which three sides are constructed of wood and the fourth side consists of a screen which is pulled down only in rainy weather; perfect ventilation being thus insured. In the main building there are arrangements for sunbaths and hydrotherapeutic applications.

TEMPERATURE: The laws are not specific. On recommendation of Dr. R. M. officials tuberculosis has been included in the "dangerous to public health." Most excellent

educational propaganda through recommendations, circulars, and "Teachers' Sanitary Bulletin" have been made; 20,000 school teachers have been supplied with the latter. There are no special hospitals, sanatoria or special dispensaries; no society for the prevention of tuberculosis. No bovine laws providing for systematic inspection. If a case of tuberculosis in an animal is reported to the State Live Stock Commission the latter is not legally bound to take action for the protection of the bovine species, but only to restrict the spread of the disease among animals. Reported by Henry B. Baker, M.D., Secretary State Board of Health.

MINNESOTA: No specific laws, but general laws permit tuberculosis to be classified among contagious diseases. No recommendations, ordinances or circulars. A special hospital for tuberculous prisoners. No special dispensaries. State institution isolates consumptives as far as practicable. Legislative committee has been appointed with the object of establishing a state sanatorium. No society for the prevention of tuberculosis. There are good bovine laws. Reported by H. M. Bracken, M.D., Secretary State Board of Health.

MISSISSIPPI: No laws or regulations concerning tuberculosis in man. No special recommendations, ordinances, or circulars. A special hospital for the tuberculous insane at Jackson. No society for the prevention of tuberculosis; no bovine laws. Reported by J. F. Hunter, M.D., Secretary State Board of Health.

MISSOURI: No laws or regulations concerning tuberculosis in man; no special recommendations, circulars, etc.; no sanatoria, special hospitals or special dispensaries. Tuberculosis Medical Society of the City Hospital Alumni of St. Louis. The State Board of Agriculture enforces the bovine laws. Reported by A. W. McAlester, M.D., Secretary State Board of Health.

At the time this report was received no other society existed; recently, however, a Missouri State Society for the Prevention of Tuberculosis has been formed.

MONTANA: No special law regarding tuberculosis, but a general law providing that all infectious and contagious diseases are reported. No recommendations or circulars as yet. The State Board of Health is engaged in finding out the prevalence of the disease. No special hospitals, sanatoria, or special dispensaries. No society for the prevention of tuberculosis. Most excellent bovine laws, including meat and milk inspection law, in operation. Reported by A. F. Longeway, M.D., Secretary State Board of Health, and M. E. Knowles, State Veterinarian.

NEBRASKA: No laws or regulations concerning tuberculosis in man; no ordinances or circulars; no sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis; no bovine laws. Reported by B. F. Crommer, M.D., ex-Secretary State Board of Health.

NEVADA: No laws or regulations concerning tuberculosis in man; no ordinances or circulars; no sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis; no bovine laws. Reported by S. C. Gibson, President State Board of Health.

NEW HAMPSHIRE: No special laws or regulations. Circulars, papers and addresses on the restriction and prevention of tuberculosis have been widely distributed. A commission for the establishment of a state sanatorium has been created. A "Suncook Association for the Prevention of Tuberculosis." Good bovine laws. Reported by Irving A. Watson, M.D., Secretary State Board of Health.

NEW JERSEY: Numerous local boards have anti-spitting laws. One city requires the reporting of cases of pulmonary tuberculosis. A good circular on "Consumption, Its Communicability and Prevention," has been issued. No sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis. Good bovine laws. Reported by Henry Mitchell, M.D., Secretary State Board of Health.

NEW MEXICO: According to the direct report of Dr. W. G. Hope, the Secretary of the Territorial Board of Health, the only law is one appertaining to contagious diseases. But, according to Mr. Reynolds, secretary of the territory, there is a law in force relating to tuberculosis in human subjects, being

a portion of the school law which requires that all teachers in the public schools furnish a physician's certificate, stating that they are not afflicted with the above-mentioned disease. Circulars of instruction are distributed to tuberculous persons and to those in contact with them. United States Marine Hospital for tuberculous sailors at Fort Stanton, and United States Hospital for tuberculous soldiers at Fort Bayard; St. Joseph Hospital, Silver City. No society for the prevention of tuberculosis; no bovine laws. Reported by W. G. Hope, M.D., Secretary Territorial Board of Health.

NEW YORK: The state as a whole has no legal enactments directed especially toward the spread of tuberculosis. A circular of information has been issued for the adoption by local boards. Beside a number of institutions located in the city of New York, which will be enumerated under the respective column, there are in this state the Adirondack Cottage Sanatorium for consumptives of moderate means; the St. Gabriel's Sanatorium, at Paul Smith's, also for patients of moderate means, with some free beds; the Loomis Sanatorium at Liberty for wealthier patients, with a branch for the poorer classes; the Liberty Sanatorium, a private institution for paying patients only. There has been an appropriation of \$100,000 for a New York State Sanatorium and a place has been selected at Lake Placid for its creation. Another sanatorium is projected for consumptive working girls, by the name of Stony Wolde Sanatorium.

There is as yet no state society for the prevention of tuberculosis. Buffalo has a local association, with Dr. Benjamin G. Long as president, and Dr. Wm. G. Bissell as secretary. A special committee on the prevention of tuberculosis has, however, been formed under the direction of the New York City Charity Organization Society, which has the coöperation of a number of prominent physicians of the city and state. The excellent work which was started by the same society on behalf of tenement-house reform gives rise to the hope that a state commission on tuberculosis may result from this work. The enforcement of good bovine laws is in the hands of the Department of Agriculture of the State of New York, and \$10,000 have been appropriated for that purpose. Reported by Daniel Lewis, M.D., Commissioner of Health, and William Henry Kellye, State Veterinarian.

NORTH CAROLINA: No special legislation, except some local anti-spitting laws. An article on the prevention of tuberculosis is widely circulated, so is a monthly bulletin containing articles on the same subject. Winyah Sanatorium at Asheville. No society for the prevention of tuberculosis; no bovine laws. Reported by Richard H. Lewis, M.D., Secretary State Board of Health.

From an unofficial source and last year's report of Dr. Amblor I learn of the existence of two other private sanatoria in that state, namely the Pigbone Sanatorium, for colored consumptives, and St. Joseph's Retreat.

NORTH DAKOTA: No laws or regulations concerning tuberculosis in man; no ordinances or circulars; no sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis; no bovine laws. Reported by H. D. Quarry, M.D., Secretary State Board of Health.

OHIO: Special laws are now before the legislature. A good circular is issued. A bill has been introduced for the appointment of a state tuberculosis commission to report on the feasibility and advisability of establishing sanatoria. The Cincinnati Hospital for Consumption, in charge of Dr. Lyle. Ohio Society for the Prevention of Tuberculosis: president, Hon. J. H. Outhwaite; secretary, Dr. Andrew Dimberman. Good bovine laws. Reported by C. O. Probst, M.D., Secretary State Board of Health.

OKLAHOMA: No laws or regulations concerning tuberculosis in man; no ordinances or circulars; no sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis; no bovine laws. Reported by L. Haynes Buxton, M.D., Secretary Territorial Board of Health.

OREGON: No laws or regulations concerning tuberculosis in man; no ordinances or circulars; no sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis; no bovine laws. No state board of health. Reported by J. A. Fulton, M.D., Health Officer.

PENNSYLVANIA: No laws or regulations concerning tuberculosis in man. A cautionary circular for the instruction of the public has been issued. Hospital for Consumptives, Chestnut Hill Hospital, Rush Hospital for Consumptives, all in Philadelphia; Free Hospital for Poor Consumptives; Sunnyrest Sanatorium, White Haven. Pennsylvania Society for the Prevention of Tuberculosis, president, Dr. Howard S. Anders; secretary, Dr. Alexander H. Davisson. Excellent bovine laws. Reported by Benj. Lee, M.D., Secretary State Board of Health.

From an unofficial source I learned that a movement is about to be started in Pennsylvania to collect \$5,000 by public subscription to be expended in the erection and maintenance of suitable shelters on the state forest reservations, where consumptives, indigent or in comfortable circumstances, may go for curative treatment. Recognizing the value of the state's woodlands to the health of the community, Dr. J. T. Rothrock, Commissioner of Forestry, took a consumptive family from the city of Philadelphia and placed them in the mountain air of Monroe County, near Resica, where the elevation is about 1,200 feet. The excellent results obtained with this single family have given rise to the desire to try the experiment on a larger scale.

RHODE ISLAND: No special state legislation, but local anti-spitting laws in Providence, Pawtucket and Woonsocket. No circulars distributed, except those sent out with the bottles which are intended for the collection of sputum, and those circulars which are sent out with a positive report. An appropriation of \$1,500 is made annually available for examination of sputum for physicians. No sanatorium, special hospitals, or special dispensaries. Bill before legislature asking for an appropriation of \$100,000 for the erection of a state sanatorium is in the hands of a judiciary committee. No society for the prevention of tuberculosis. Bovine law defective; it permits the farmer to utilize his animals for milk production until they are in the last stages of the disease, and, failing to give milk, are of no value to the farmer; he then sells the diseased carcass to the state, for which he gets half of the appraised value. Reported by Gardner T. Swarts, M.D., Secretary State Board of Health.

SOUTH CAROLINA: No special legislation; some cities have anti-spitting laws. Good circular has been issued. No sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis; no bovine laws. The combat of bovine tuberculosis is in the hands of the Clemson Agricultural and Industrial College. Reported by James Evans, M.D., Secretary State Board of Health.

SOUTH DAKOTA: No laws or regulations concerning tuberculosis in man; no ordinances or circulars; no sanatorium, special hospital or special dispensary; no society for the prevention of tuberculosis; no special bovine laws. Tuberculosis comes under the head of contagious diseases, as does glanders, etc. Reported by Wm. Edwards, M.D., Superintendent Board of Health, and J. P. Foster, State Veterinarian.

TENNESSEE: No special legislation; the power of the health board is simply advisory. The latter has, however, urged additional legislation in regard to tuberculosis. No recommendations, circulars, etc.; no sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis. The following resolution of the board of health concerning tuberculosis in animals has been widely distributed:

Resolved, That this Board hereby gives notice that all persons are prohibited from selling milk, or other dairy products intended for human food, from cattle infected with either tuberculosis, anthrax (charbon) or glanders.

All persons are prohibited from skinning, selling, or otherwise making use of any part of any animal dead from anthrax (charbon) or glanders, and from throwing such dead animal into any pond, lake or running stream.

Reported by J. A. Albright, M.D., Secretary State Board of Health

TEXAS: No laws or regulations concerning tuberculosis in man; no ordinances or circulars; no sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis; no bovine laws. Reported by Geo. R. Tabor, Secretary State Board of Health.

From an unofficial source we learn of the excellent work the agricultural colony of tuberculous prisoners of the state of

Texas has accomplished. A large number of the prisoners have been cured and an equally large number very much improved. During the first year \$25,000 remained as net earnings of this philanthropic enterprise. Last year Dr. Ambler reported the existence of Dr. L. W. Cook's Sanatorium at Boerne.

UTAH: No special laws against the spread of tuberculosis from man to man. The board of health issues a revised statute relating to the public health, however, only with reference to bovine tuberculosis. No sanatoria, special hospitals or special dispensaries. Reported by T. B. Beatty, M.D., Secretary State Board of Health.

VERMONT: No special laws concerning tuberculosis in man. An excellent circular for information is issued. No sanatorium, special hospital or special dispensary; no society for the prevention of tuberculosis. No definite information concerning bovine tuberculosis could be procured, but I learned indirectly that the state kills tuberculous cattle and recompenses the owner. Reported by H. D. Holton, M.D.

VIRGINIA: No special laws; an excellent circular on the restriction and prevention of consumption is issued; no sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis; no bovine laws. Reported by Paulus A. Irwin, M.D., Secretary State Board of Health.

WASHINGTON: Every case of tuberculosis must be reported, just as any contagious disease. A good circular is issued, remarkable for its plain language concerning unsanitary ladies' dress. No sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis. Reported by D. C. Newman, M.D., Secretary State Board of Health. Concerning bovine laws no information has been received.

WEST VIRGINIA: No answer has been received.

WISCONSIN: No specific laws. Good, brief circular, small so as to be enclosed in letters. No sanatoria, special hospitals or special dispensaries, but a bill to provide a state sanatorium is before the legislature. Efforts are being made to form a society for the prevention of tuberculosis. Most excellent bovine laws. The Live Stock Sanitary Board has full power to do everything toward the eradication of bovine tuberculosis. Reported by U. O. B. Wingate, M.D., Secretary State Board of Health.

WYOMING: No laws or regulations concerning tuberculosis in man; no ordinances or circulars; no sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis; most excellent bovine laws. Reported by Amos W. Baker, M.D., Secretary State Board of Health.

REPORTS FROM VARIOUS CITIES.

From the city boards of health of the 43 largest cities in the Union I received only the following 25 replies:

New York: Section 153 of the Code of New York reads as follows:

That pulmonary tuberculosis is hereby declared to be an infectious and communicable disease, dangerous to the public health. It shall be the duty of every physician in this city to report to the Sanitary Bureau, in writing, the name, age, sex, occupation and address of every person having such disease who has been attended by or who has come under the observation of such physician for the first time, within one week of such time. It shall also be the duty of the commissioners or managers, or the principal superintendent or physician of each and every public and private institution or dispensary in this city to report to the Sanitary Bureau, in writing, or to cause such report to be made by some proper and competent person, the name, age, sex, occupation and last address of every person afflicted with this disease who is in their care or who has come under their observation within one week of such time. It shall be the duty of every person sick with the disease and of every person in attendance upon anyone sick with this disease, and of the authorities of public and private institutions or dispensaries, to observe and enforce all the sanitary rules and regulations of the Board of Health for preventing the spread of pulmonary tuberculosis.

While physicians are requested to report their private as well as hospital cases, no inspector visits the premises of the patient unless the attending physician makes the request. The law referring to the spitting nuisance is announced by placarding the following in elevated and surface cars:

Spitting on the floor is a misdemeanor; \$500 fine or imprisonment for one year, or both, may be the punishment therefor. By order of the Board of Health. Section 194, Sanitary Code; Section 15, Penal Code.

The cards for reporting private cases read as follows:

REPORT OF CASE OF TUBERCULOSIS.

New York, ... 190..
 Name of patient, ... Age Sex
 Occupation Residence
 Previous cases in family, and relation to patient
 Do you wish an inspector to visit the premises and instruct the family regarding prophylaxis? Answer yes or no
 M.D.
 Residence

NOTE.—Cases of tuberculosis will NOT be visited by an inspector from the Department of Health except on the request of the attending physician.

Bacteriologic examination is made free of charge. An excellent circular, entitled "Information for Consumptives and Those Living with Them," has been issued in English, German, Italian and Hebrew and largely distributed. There is no society for the prevention of tuberculosis, but a special committee for the prevention of tuberculosis has been recently formed under the direction of the New York Charity Organization Society with a view of creating a permanent tuberculosis commission, similar to the Tenement-House Commission. Section 135 of the Sanitary Code of New York, referring to diseased animals, reads as follows:

That no diseased or sickly cattle, swine or sheep, nor any horse, dog or cat which is suffering from or has been exposed to any disease which is contagious among such animals, shall be brought into or held or kept in the City of New York. All persons, corporations or companies bringing milk cows into the City of New York shall furnish a certificate signed by a veterinarian who is a graduate of a recognized veterinarian college, with the date of graduation and the name of college from which the degree was received, to the effect that said cows are free from tuberculosis as far as may be determined by physical examination and the tuberculin test. Said certificate shall give a number which has been permanently attached to each cow, and a description sufficiently accurate for identification stating the date (which must be not more than sixty days prior to the time they are brought into the city), the place of examination, the temperature of the cow or cows at intervals of three hours, for twelve hours before the subcutaneous injection of the tuberculin, the preparation of the tuberculin used, the location of the injection, the quantity injected, the temperature at the tenth hour after the injection of the tuberculin and every three hours after the aforesaid tenth hour for twelve hours, or until the reaction is completed. No cow with a certificate which states that said cow gave a reaction of two degrees F. after the injection with 5.5 c.c. of the tuberculin prepared by the Department of Health of the City of New York (or its equivalent), diluted with ten times its volume of a 5 per cent. watery solution of carbolic acid, shall be brought into the City of New York.

There is an excellent law protecting the inhabitants of the City of New York against unwholesome, impure and adulterated milk. Reported by Prof. Hermann M. Biggs, M.D., Health Officer.

An additional report concerning the hospital accommodation for the consumptive poor of the City of New York has kindly been sent to me by Hon. Homer Folkes, the Commissioner of Public Charities. The Seaton Hospital receives \$60,000, St. Joseph's Hospital \$50,000, and the Brooklyn Home for Consumptives \$15,000 per year for the care of consumptives, at the per capita rate of 80 cents per day. Through this appropriation the public charities dispose of:

210 beds per year at Seaton Hospital.
 170 beds per year at St. Joseph's Hospital.
 52 beds per year at Brooklyn Home for Consumptives
 432 beds.

In addition to these there are beds set aside for consumptives in the Department of Public Charities:

50 beds at the Kings County Hospital.
 120 beds at the Almshouse.
 295 beds at the Metropolitan Hospital.

465 beds.

That is a total of 897 beds at the disposal of the commissioner for the care of the consumptive poor of the City of New York.

In addition to this report, I beg to state that St. Joseph's Hospital can accommodate 350 patients, Seaton Hospital 250, the Brooklyn Home for Consumptives 75, the Loomis City Sanatorium 20, and the Montefiore Country Sanatorium 150 patients. The Lincoln (formerly colored) Hospital has a special building for consumptives with about 40 beds. The Home of Rest for Consumptives, which up to recently accommodated a number of patients in a special ward at St. Luke's Hospital, has acquired a new property and hopes to accommodate about 30 patients by July 1. The only tuberculosis dispensary which

to my knowledge is exclusively devoted to the treatment of ambulant tuberculous patients is the one connected with the New York Throat and Nose Hospital.

CHICAGO: Anti-spitting law. Circular and postal-card report for physicians reporting deaths from tuberculosis. The county poorhouse has separate pavilions; the Alexian Brothers' Hospital a ward for consumptives. St. Elizabeth's Hospital for 400 consumptive patients is in course of construction. No special city bovine laws. Reported by Arthur R. Reynolds, M.D., Commissioner of Health.

PHILADELPHIA: No special laws. A good circular on the means of preventing the spread of consumption is published. Rush Hospital and Chestnut Hill Hospital. No city society for the prevention of tuberculosis. No city bovine laws or regulations. Reported by J. Howard Taylor, M.D., Medical Inspector.

BOSTON: Section 79 of Chapter 80, of the Public Statutes, reads as follows:

When a physician knows that a person whom he is called to visit is infected with any disease dangerous to the public health, he shall immediately give notice thereof to the board of health of the town; and if he refuses or neglects to give such notice he shall forfeit for each offense not less than fifty nor more than one hundred dollars. The Board of Health considers tuberculosis an infectious disease and requires all cases to be reported. In cases where isolation or care can not be had the patient is removed to a hospital. In case of death or removal of the patient the rooms are promptly fumigated.

Excellent directions for consumptives and those living with them are issued and widely circulated. Bacteriologic examination made free of charge. The following institutions already mentioned under Massachusetts are located in Boston: Carney Hospital (special wards for consumptives); Channing Home (for poor women and children), 17 beds; Cullis Consumptives' Home for the Poor, 44 beds; Free Home for Consumptives; House of the Good Samaritan (for women and children), 28 beds. No society for the prevention of tuberculosis. Excellent regulations concerning bovine tuberculosis and products from diseased cows. Reported by C. E. Davis, Jr., M.D., Secretary Board of Health.

CLEVELAND, OHIO: Anti-spitting law in street cars. Disinfection with formaldehyd gas is enforced after every case of death from tuberculosis. A special hospital for tuberculous patients is planned by the city. There is a city branch of the Ohio State Society for the Prevention of Tuberculosis. No measures against bovine tuberculosis. Reported by Martin Friedrich, M.D., Health Officer.

SAN FRANCISCO: All cases of tuberculosis must be reported. There is an anti-spitting law. The law also requires the fumigation of premises inhabited by the poor where death resulted from tuberculosis. A regulation of the school department rejects applicants for teacher's certificates to those affected with tuberculosis and makes the same cause for dismissal of teacher. No circulars issued. No sanatoria, special hospitals or special dispensaries. No society for the prevention of tuberculosis. Good bovine laws directed against the spread of tuberculosis in cattle and the sale of tuberculous products, milk and meat. Reported by J. G. Emory, Secretary Board of Health.

CINCINNATI: Anti-spitting law. No circulars of information are issued. Has the first municipal tuberculosis hospital in the United States. No society for the prevention of tuberculosis; no bovine laws. Reported by Clark W. Davis, M.D., Health Officer.

PITTSBURG: Anti-spitting law. No circular of information, but gratuitous bacteriologic diagnosis. No sanatoria, special hospitals or special dispensaries. No local society. Strict bovine laws which were confined to the city limits and have driven dairies outside beyond the control of the authorities. Reported by E. G. Matson, Health Officer.

DETROIT: Mr. John F. McKinlay, Secretary of the Board of Health, reported to me in substance as follows: "In compliance with an order issued by the State Board of Health the Detroit Board sought to enforce the order that cases must be reported to the health officer. The board gave encouragement to physicians to report this disease and analyze sputum gratis when requested. Dr. E. L. Shurly refused to report so that the courts might pass on the validity of the order of the state board. Dr. Shurly was fined \$50 and costs. An appeal was

taken to our state supreme court and the case was some time ago submitted, but as yet no opinion has been handed down. After this litigation was begun, no further reports were made, circulars distributed, or anything else in that connection done, and no effort made by our board to enforce the state board order. If the court sustains the order, then, of course, consumption is contagious and must be so treated by all concerned. The circular, such as was in use before the Shurly case arose, is good. It is entitled "Information for Consumptives and Their Families." No sanatoria, special hospitals or special dispensaries. No society for the prevention of tuberculosis. No local bovine laws.

NEW ORLEANS: Sidney L. Theard, M.D., Secretary of the Board of Health, replied to all five questions in the negative.

MILWAUKEE: No laws or regulations concerning tuberculosis in man. Reporting of cases is not compulsory. Good rules for consumptive patients circulated. Bacteriologic examination made gratuitously for physicians. No sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis; no bovine laws. Reported by F. M. Schultz, M.D., Commissioner of Health.

ST. PAUL: No laws except anti-spitting ordinance. No circulars; no sanatorium, special hospital or special dispensary; no society for the prevention of tuberculosis. Milk supply controlled and cattle tested. Reported by Gustav A. Renz, M.D., First Assistant Health Commissioner.

FALL RIVER, MASS.: Anti-spitting law. There seem to be no circulars issued, but the board of health attends to the gratuitous bacteriologic examination of sputum. Dr. Richards informs me that there is a movement on foot for the establishment of a municipal sanatorium. No society for the prevention of tuberculosis. No report received concerning bovine laws. Reported by Samuel B. Morriss, Sanitary Inspector.

INDIANAPOLIS: No laws or regulations concerning tuberculosis in man. State board circulars of information are distributed. No sanatorium, special hospital or special dispensary. No society for the prevention of tuberculosis. No bovine laws. Reported by Eugene Buehler, M.D., Secretary Board of Health.

LOUISVILLE, KY.: Cases of tuberculosis are made reportable. Ordinances for informing the public have not been adopted, but frequently recommended. No sanatorium, special hospital or special dispensary. No society for the prevention of tuberculosis. Ordinances requiring dairy cattle to be examined every three months and if necessary by tuberculin. Reported by M. K. Allen, M.D., Health Officer.

MINNEAPOLIS: No special laws; seemingly no circulars, etc.; no sanatorium, special hospital or special dispensary; no society for the prevention of tuberculosis. Rigid inspection of cattle from which milk supply is obtained; every herd is tested once a year. Reported by P. M. Hall, M.D., Commissioner of Health.

NEW HAVEN, CONN.: Consumption is declared an infectious and communicable disease and dangerous to the public health. Rooms are to be disinfected after removal or death of patient. No circulars; no special institutions; no society for the prevention of tuberculosis; no municipal bovine laws. Reported by Ward Bailey, Clerk Board of Health.

PROVIDENCE, R. I.: No laws or regulations concerning tuberculosis in man, except anti-spitting ordinance; no circulars, etc.; no sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis; no bovine laws. Reported by Charles V. Chapin, M.D., Superintendent of Health.

ROCHESTER, N. Y.: Cases are made reportable, but no inspection of cases is made by the health department, nor any restrictive measures enforced. An excellent circular on the prevention of consumption is issued. No sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis, but the Rochester Public Health Association is doing the usual work of such societies. No bovine laws. Reported by Geo. W. Goler, M.D., Health Officer.

SYRACUSE, N. Y.: Anti-spitting law. Physicians are requested to report cases, but no isolation attempted. Excellent circular for information of consumptives and those living with them has been placed in every house in the city. No sanatoria,

special hospitals or special dispensaries; no society for the prevention of tuberculosis. Excellent bovine laws. Reported by B. S. Moore, M.D., Health Officer.

TOLEDO, OHIO: Fumigating of house after death of patient. State board circulars are distributed. No sanatoria, special hospitals or special dispensaries; no society for the prevention of tuberculosis; an excellent milk ordinance. Reported by W. W. Brand, M.D., Health Officer.

ST. JOSEPH, Mo.: No laws or regulations except anti-spitting ordinance; no circulars, etc.; no special institutions; no society for the prevention of tuberculosis; no bovine laws reported. Reported by H. N. Keener, M.D., Clerk Board of Health.

LOWELL, Mass.: H. H. Knapp, Agent, replied to all five questions in the negative.

ALBANY, N. Y.: Anti-spitting law. Circular is sometimes sent when cases are voluntarily reported. No special institutions; no society for the prevention of tuberculosis; no bovine laws. Reported by Joseph D. Craig, M.D., Health Officer.

CAMBRIDGE, Mass.: Anti-spitting law; no circulars. Gratuitous bacteriologic examination of sputum; no special institutions; no society for the prevention of tuberculosis; no bovine laws. Reported by James B. Sloper, Clerk Board of Health.

THE ANSWERS SUMMARIZED.

A summary of the answers reveals the fact that 3 states and 4 cities make the reporting of cases of tuberculosis obligatory, 5 states and 5 cities optional; in 1 city (Detroit) the matter is under litigation. Two states have general anti-spitting laws, 5 states report local and 13 cities individual anti-spitting laws. Twenty-two states and 7 cities issue circulars and recommendations. The United States government has 2 sanatoria, 5 states have 5 special state institutions (Maryland, State Hospital; Massachusetts, State Sanatorium; Minnesota, Hospital for Tuberculous Prisoners; Mississippi, Hospital for Tuberculous Insane; Texas, Agricultural Colony for Tuberculous Prisoners). Nine states have projected state sanatoria, viz., Connecticut, Louisiana, Maryland, Minnesota, New Hampshire, New York, Ohio, Rhode Island, Wisconsin. Tent colonies for tuberculous patients are reported to exist only in Massachusetts and Pennsylvania. Only 3 cities (New York, Chicago and Buffalo) have special municipal consumptive hospitals. Boston cares for its poor in the various private institutions; New York, besides its hospital on Blackwell's Island, maintains likewise a large number of tuberculous patients in private institutions. Only one city has a special tuberculosis dispensary. Eleven states have a total of 42 private institutions, some are supported by private charity, some partially self-supporting and some are for paying patients only. Five states have state societies, 5 cities have city societies for the prevention of tuberculosis and one city (New York) has a special committee for the same purpose. Twenty states have special laws to combat bovine tuberculosis, and 12 cities have their own bovine laws. Three states have no boards of health. Twenty states have done nothing regarding tuberculosis in man or beast; 6 states have only done something regarding tuberculosis in man and nothing in beast, and 8 states have only done something regarding tuberculosis in beast and nothing in man.

REMARKS ON CONDITIONS IN VARIOUS STATES AND CITIES.

Now let us in the spirit of kindness review some of the reports received, showing the works which the various boards of health are doing, and see what we can learn from their defects or how profit by their excellencies.

The first dissimilarity which confronts us is in the various laws relating to the reporting of cases of tuberculosis to the respective health authorities. I would

suggest that in the interest of demographic and statistical science and in the hope of the discovery of some of the underlying causes of the disease when it is seemingly confined to certain districts, houses or families, that all cases of pulmonary or laryngeal tuberculosis should be reported. These reports should, however, be confidential, not on postal cards, but in letters, and the records should not be open for inspection except with authorization of the head of the department and for valid reasons. On receiving a report from a physician the health department should send to him, enclosed in an envelope, printed general hygienic and prophylactic instructions, to which the physician in charge of the patient should attach his signature. To these printed instructions the physician can add his verbal advice.

While disinfection at regular intervals of the rooms during the lifetime of the patient would be the ideal method, the advisability of more or less disinfection of the rooms must be left to the discretion of the attending physician. The disinfection of rooms after removal or death should, however, be obligatory, particularly in hotels, boarding houses, health resorts, hospitals and sanatoria. There should be no charge for disinfection for the poor. A sanitary inspector should only have the right to visit the premises of the patient when the attending physician or the family desires to have this done. On the other hand, it would seem to me a vital duty of the board of health to inspect regularly all institutions which admit cases of pulmonary tuberculosis for treatment and care, and to insist on a systematic execution of all the necessary precautions concerning the prophylaxis of consumption. All those of you who have visited, as I have done, many of the so-called "homes" or "hospitals" for consumptives, some even sailing under the name of "sanatorium," where there is often not even a visiting, much less a house physician, will bear me out in the statement that these institutions may constitute a great danger to the community. No matter how devoted the priest, minister, sister superior or matron may be in supervising the "home," in an assembly of consumptives to carry out the hygienic and prophylactic measures requires the strong will and the thorough medical knowledge of the physician especially trained for such an important position.

The board of health which makes the reporting of tuberculous cases compulsory must, however, also be prepared to offer hospital accommodations for any case which may be reported to the health officer as in urgent need of isolation, as, for example, when the attending physician considers the environments of the consumptive such that proper precautions against infection can not be carried out.

(To be continued.)

The illustrated conclusion of Dr. Knopf's paper will appear next week. This is the opening article of the Symposium on Tuberculosis. The other articles which will appear, with the discussions thereon, in the succeeding issues are as follows:

ESSENTIALS IN THE CONSTRUCTION OF HOSPITALS FOR LARGE CITIES.*

A. J. OCHSNER, B.S., F.R.M.S., M.D.

Surgeon in chief of Augustana Hospital and St. Mary's Hospital.
Professor of Clinical Surgery in the Medical Department
of the Illinois State University.
CHICAGO.

Almost every large city in this country has under contemplation the construction of one or more hospitals at the present time, and during the next few years hundreds of these public institutions will be constructed in this country. This will involve the expenditure of many millions of dollars, and will produce good or bad facilities for the treatment of millions of patients in the future. If these institutions are properly planned, the amount of good which will accrue to the citizens of this country for the amount of money expended will be vastly greater than if they are badly planned. The good features of a well-planned hospital will have a permanently beneficial effect on the community supporting the institution, and in the same manner a badly planned hospital will be a constant source of inconvenience, if not a real menace. For these reasons it seems proper for this subject to be discussed by the representative surgeons and hospital men who compose, to a great extent, the Surgical Section of the American Medical Association.

THE COMMON BASIS OF HOSPITAL CONSTRUCTION.

Singularly enough, the work most extensively consulted by architects who are called on to provide the plans for hospitals, is "Hospital Construction and Organization." "The Johns Hopkins Hospital, 1875," is one which was based on observations made 27 years ago. The authors of these essays did their work so well that no one has seriously attempted to criticise them since, and the work has stood with authority for these many years. One can obtain a fair idea of how thoroughly the plans and theories laid down in these essays have been accepted by architects who have been called on to plan hospital buildings by the comprehensive work of Henry C. ... and Asylums of the World, J. A. Churchill, London, 1893." This work gives the plans of all the important hospitals which were constructed before the close of its publication, and virtually all of these contain the same essentials in their construction.

THE NEED OF NEW PRINCIPLES IN CONSTRUCTION.

When we bear in mind that during this time everything in our theories concerning infection, contagion and hygiene has changed, and that scientifically proven facts have taken the place of theories, does it not seem strange that we should still adhere to the same essentials in hospital construction? Could an architect build an office building to-day on essentially the lines of thirty years ago, or a hotel or a factory or a library or a brewery or a building utilized for any industry in which there has been progress?

This work was written before we were acquainted with the cause of infection; before we knew that infection means the planting by contact of definite micro-organisms; before we knew that these micro-organisms develop under definite conditions, and that their development can be prevented or inhibited at our will. It is true that Pasteur had opened the way to our present conception of infection before this time, but his theories had not yet taken a definite practical form. At that

time observation had demonstrated the fact that if one patient in a given part of a hospital became infected, the other patients were likely to suffer in the same manner and that patients in another building at a distance might remain free from the infection, consequently it seemed wise to separate as much as possible the patients in separate pavilions. At the present time we know that the infection was carried from one patient to the other through the ignorance of the attendant who manipulated all the patients in the same pavilion, but could not contaminate those with whom he did not come in contact. This fact is so well understood now that it seems superfluous to mention it. Every one connected with hospital work is drilled on this fact so that in well-regulated hospitals infection of wounds in the same pavilion is no more likely than it would be if they were any given distance apart.

THE GENERAL PLAN.

A knowledge of this fact should eliminate the construction of hospitals extending over large areas, if there were no other reason except the fact that there is greater economy in construction and maintenance of a compact building. A compact building can be heated at a smaller expense, the food can be supplied to the patients more easily and with less labor, hence more economically; the amount of cleaning and painting and repairing is decreased. There is less roof surface exposed, and the time of the visiting staff is economized because the attending physicians and surgeons are not compelled to travel great distances in visiting the patients in different wards.

Ever since Pasteur's observations determined the presence of micro-organisms in the ordinary air and their absence in the air on high mountains, it has become more and more apparent that the air near the surface of the earth contains more micro-organisms than that higher up. This is especially true in cities in which the street dust is laden with germs and is much thicker at the level of the first than at the level of the higher stories. Our own observations have again confirmed this well-established fact. This fact must condemn low hospital buildings, because in these the patients are forced to live in the most unfavorable conditions as regards the air they are compelled to breathe. This fact, although already discovered by the observations of Pasteur and his pupils, had not been generally considered when the Johns Hopkins essays were published, but now that we are familiar with this fact it seems unfortunate that it is not generally made use of in hospital construction. The same principle applies to the building of operating rooms. A number of palatial operating pavilions have been constructed on the ground floor in great cities, whereas they should have been placed in the garret of a tall building.

FIRE-PROOF CONSTRUCTION.

Twenty-five years ago it was not wise to build high hospital buildings because of the danger from fire. This danger no longer exists because absolutely fire-proof buildings can now be easily constructed out of stone, brick, tile, concrete and steel. It is true that some so-called fire-proof buildings have been burnt, but never those which were honestly constructed, in which there was no wood used except for floors and window frames and doors, and in which each story was separated from the one above by a ceiling of hollow tile or concrete in which the steel was imbedded. Of course all of the partitions, closets and air shafts must be constructed of hollow tile or cement, and in fact there must be no wood

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard.

except in the floors, doors and windows, and even these parts can be made of fire-proof material.

A hospital not constructed absolutely fire-proof at the present time should be condemned, even though it be only one or two stories high. This is especially true because at the present time a hospital is likely to contain

LOCATION AND ARRANGEMENT OF DEPARTMENTS.

These are the main considerations and all these are relatively new and should be borne in mind in the construction of hospitals at the present time. The minor considerations will be treated later, not because they

a very large proportion of patients, who have just undergone serious operations and could consequently not be moved with safety in case of fire. The use of the modern elevator is another important factor which makes high hospital buildings especially convenient.

are unimportant, but because I wish to emphasize the greater importance of the adoption of high hospital buildings for large cities. With a given area of land on which to build, it is plain at once that with a high building many favorable con-

ditions can be secured which will be impossible with low buildings of the same number of beds.

1. The building can be set back from the street, which will still further lessen the amount of street dust. It will also lessen the disturbance caused by the street noise.

2. If land can be secured overlooking a park or any other attractive landscape, the higher the building the more patients can obtain a view of this landscape.

3. The building can be more easily placed so that every room and every ward secures sunlight during some portion of the day. With the low buildings one is constantly compelled to infringe upon the sunlight in order to secure a sufficient amount of space for the number of beds required, while with the high buildings one simply adds another story which in no way interferes with the remaining portion of the building.

4. The hospital can be conveniently located for the patient as well as for desirable physicians and surgeons for its staff. Relatively speaking, the air above the second story in a well-chosen portion of the city in

VENTILATION.

In the climate of the United States the air supply of the hospital must come during the warmer portion of the year directly from the outside through open windows or through ventilating flues in the walls. During the colder part of the year the fresh air should be forced into the upper portion of the wards and rooms by means of revolving fans. This air should be taken from a tower above the roof.

It should first be washed by passing through strands of oakum or other similar material suspended in the horizontal portion of the air-shaft, a small amount of water being permitted to trickle over these strands constantly; then it should pass through a long shaft, extending preferably through the entire length of the building. This shaft should contain coils heated with steam or water. The outside of this shaft should be covered with some material which prevents the radiation of heat, in order to economize fuel. Taking the air from a tower some distance above the roof of a high building, it is nearly free from micro-organisms;

Fig. 3.—Augustana Hospital. Plan of second and third floors.

which the surrounding buildings are not high compares favorably with the air in the first story in the outskirts of a large city. And the air in the sixth story is nearly as pure as country air.

If a great physician or surgeon can be saved an hour's time each day which he would be compelled to spend in going to and from the hospital located a great distance from his residence, his services can more easily be obtained, and this time in itself given a hospital service will amount to a great deal during each year. There can also be no doubt that much harm is done to many very acute cases by being carried great distances to the hospital. I need but mention those suffering from severe pneumonia, typhoid fever or peritonitis.

Of course the same care should be exercised in selecting a location. It should be as high as possible, near a park, river or lake in as quiet a location as available, away from the street cars or railroad tracks and still easily accessible to patients and their friends. The larger the grounds the better it is for the institution.

this can be freed from particles of soot and introduced into the hospital clean and heated to the desired temperature. The foul air should be carried out of the rooms and wards through flues opening near the floor.

In portions of the country with especially severe winters this system of heating may be combined with direct radiation from steam or hot-water coils, only enough air being forced through the heated air-shaft for ventilation, the greater portion of the heat being supplied by the more economical direct radiation.

A very simple method devised for heating and ventilating is the direct, indirect method, one which has been used to some extent in hospitals. The heating is all direct, the air coming in through louvers, passing through a register which can be opened or closed at will, back of which is an extremely fine mesh screen which is removable, so that it can be readily cleaned. All the air goes into a duct, two screens made of cheese cloth and removable being interposed. These can be made damp and changed as required. At the bottom of the duct are two small doors into which can be placed a pan

of water. This will serve the double purpose of taking up the particles which may get in and of giving humidity to the air. The air falls directly over the radiator through the duct, and this duct being back of the radiator, the chill is taken off the air primarily. It then rises and traverses the entire room to the duct at the floor which leads to a large air chamber in the attic space between ceiling and roof, giving room for a great volume and thus a regular circulation. This attic space is ventilated by a shaft thirty feet above the roof and may be made to work either naturally or mechanically, the first by means of a cowel facing the aperture from the wind and so creating a vacuum directly in front, and a plenum state directly behind the shaft. A simple mechanical process is the placing of a radiator of large capacity at the base of the shaft or duct and so creating a current of air by convection. An ordinary gas jet at the bottom of each shaft will in many instances suffice. This method has many strong advocates.

LIGHTING ARRANGEMENTS.

If a hospital building is placed from north to south, being long and only wide enough for a row of wards or rooms on each side of a central hall, then all the

Fig. 4.—St. Mary's Hospital. Part of fifth floor.

rooms and wards on one side are exposed to sunlight during the entire forenoon and on the other side during the afternoon.

In visiting many hospitals I have found that only in a few instances care has been exercised to obtain sunlight for every room and ward in the institution, and the dark corners are very common.

Ordinary illuminating gas is the least desirable of all artificial lights. It gives rise to much soot, gives off much heat and consumes much oxygen, and in most institutions it does not give a clear, uniform light unless some form of asbestos mantle is used.

Incandescent electric light is clean and does not consume any oxygen and gives off but little heat, but the radial power is not good, compared with the cost of production. Acetylene gas consumes some oxygen, but compares well otherwise with incandescent electric light; it is possibly the most economical form of lighting. There is very little heat produced and no soot.

KITCHENS.

The kitchen is one of the most common sources of annoyance in hospitals because of the odors which are

very offensive to the sick. This can be remedied by placing the kitchen in the garret. All the odors from cooking rise, hence the location of the kitchen in the garret will at once eliminate this source of trouble. The range should be placed in the center of the room and a good skylight and ventilator put over it. Another remedy lies in building a separate small building at some distance from the main hospital building for the housing of the boilers, engines, dynamos, if electric illuminating is employed, the kitchen and the laundries.

Each floor should, of course, have its own little diet kitchen, and these should be directly below the main kitchen or in such position that there will be direct communication by dumb waiter.

FLOORS.

In the halls, bathrooms, closets, kitchens, operating and dressing rooms, some form of flooring which is impermeable to moisture, such as tiling or glass, has now been generally adopted with great satisfaction, because it can be easily kept clean and is attractive in appearance. In the wards and rooms hardwood floors laid on the cement covering which isolates the floor from the lower story seems preferable. This should be covered by some dressing impermeable to moisture in order to prevent septic materials from penetrating the pores of the wood. A careful application of grain alcohol shellac closes the pores.

WALLS.

The walls should be covered with paint which prevents the plaster from becoming filled with germs. These walls can be washed and thus rendered aseptic after the rooms have been occupied by patients with suppurating wounds.

In the operating rooms and dressing rooms walls covered with tile, marble, glazed brick or glass are very attractive, but they are in no way superior to those which have been carefully covered with hard enamel paint which is impervious and acid proof.

PLUMBING.

There is no part of the construction of a hospital which requires greater care than the plumbing, but, fortunately, this branch has been so perfectly developed in house and hotel construction that any good architect whose attention has been directed toward the importance of this part of the construction will be enabled to furnish safe and satisfactory plans. One essential that should be introduced in all hospitals is a large slop sink or hopper with a water seal—in fact, an enlarged syphon-jet water closet with a large flushing tank. The utility of such a device can be seen at a glance. The aperture at the top should not be less than 24 inches square in order to prevent spilling in emptying bed pans and other utensils. The bathroom should be separated from the water closet and both should have large outside windows, and these should, if possible, reach to the ceiling, in order to light every part of these rooms from above, which will make it much more difficult for the servants to slight their work in keeping these departments clean. Storerooms should be well lighted, for often a dark storeroom serves to accumulate unclean material, because the dirt escapes detection by those in authority.

STERILIZING ROOMS FOR MATTRESSES, BEDDING, ETC.

There should be two sterilizing chambers, each sufficiently large to sterilize all the bedding and mattresses to be used for an entire week, so that while the material is being used from the chamber in which ster-

ilization has been completed the other sterilizing chamber can serve for the accumulation of the next amount of material to be sterilized. There should also be a space left set aside for airing and sunning the bedding, which may be arranged on the roof.

Sterilization of instruments, utensils, dressings, towels and operating gowns is accomplished in a most

The accompanying drawings, kindly furnished me by Messrs. Hallberg & Sturm, architects of the Augustana Hospital, and Mr. Henry J. Schlack, architect of St. Mary's Hospital, both of Chicago, illustrate the arrangement of two floors in each building. one for private patients and one for ward patients, the floors for private patients being the higher. those for ward patients

Fig. 5.—St. Mary's Hospital. Third and fourth floors.

perfect manner in the various sterilizers which can be purchased from the manufacturers of such appliances.

SOME MODEL CHICAGO HOSPITALS.

I have been interested in the building of two of the larger hospitals of Chicago which have been under my surgical management for some years. The architects who planned these institutions incorporated the ideas brought out in this paper and the results have been most

the lower floors. The first floor is occupied by offices, waiting rooms, examining rooms, laboratories, etc., so that all the patients are above the first floor.

I also show the operating rooms, which are on the sixth floor in each institution, where their construction was possible at a much smaller expense than if placed in a separate pavilion, and still the conditions are much more favorable for an aseptic operating room than they

Fig. 6.—St. Mary's Hospital. Second floor.

satisfactory. These institutions are six stories in height and extend from north to south, with a large corridor extending the entire length of the building. There are no dark corners and very few convenient places for the accumulation of dirt. These institutions furnish better air than do one or two-story buildings and still they can be conducted at a much slighter expense.

would be on the first or second floor. Of course, it would be possible to add as many more stories as might be desired in order to increase the number of beds without in any way impairing the hygienic conditions present.

During the past sixteen years I have given a great amount of attention constantly to the study of hospital construction. I have visited most of the hospitals

of the large cities in this country and Canada, as well as those in most of the large European cities, and have studied the plans of most of the other hospitals which I have not personally visited, and I am confident that the hospitals of the large city in the future must be a high building constructed on the essentials emphasized in this paper.

EXPLANATION OF ILLUSTRATIONS.

Figures 1, 2 and 3 are taken from the plans of Augustana Hospital, which is to be completed next year, only the south half being finished at the present time.

Figures 4, 5 and 6 are taken from the plans of St. Mary's Hospital, which was completed last spring.

Figure 1 shows the top floor, the greater portion of which is given up to a series of operating rooms, dressing rooms and recovery rooms, and to the kitchen and dining rooms. These departments, it will be seen, are practically isolated from each other and from the remaining portion of the hospital.

Figure 2 represents the fourth and fifth floors, which are occupied entirely by private rooms and are provided with every comfort and convenience that may be desired by private patients.

Figure 3 represents the second and third floors, which are occupied entirely by wards. The large wards at one end of the floor, I believe, are a mistake, especially in a hospital where bedside teaching is done, because of the unnecessary disturbance of a large number of patients; moreover, it is easier to obtain uniformly good nursing if each nurse has assigned to her a ward sufficiently large to occupy her time than if a large ward is under the joint care of a number of nurses. It is much better to have all the ward patients together on the same floor and all the private patients on another floor than to have them mixed, because it avoids jealousies and dissatisfaction. In this institution the second floor contains the wards for male and the third for female patients, which further simplifies the management of the institution.

Figure 4 represents the plan for the operating, sterilizing, anesthetizing, supply and dressing rooms in St. Mary's Hospital. Being placed in the top of a high building, the light and air are ideal and the expense of construction is exceedingly low.

Figure 5 represents the third and fourth floors, which are occupied by private rooms and small private wards. In this portion of the plan the large hall extending through the entire length of the building and ending in a broad veranda at each end is especially attractive.

Figure 6 represents the second floor, which is occupied by the larger general wards, with an isolation room at each end. The two central wards, with a veranda on the east side of the building, are occupied by children. The south end is occupied by women and has a large veranda, while the north end is arranged in precisely the same manner and is occupied by the men.

There are many details which are interesting but whose description would consume too much space.

710 Sedgwick Street.

DISCUSSION.

DR. H. M. SHERMAN, San Francisco—Dr. Ochsner's statement that modern methods of constructing buildings should be applied to hospitals is one to which we will all agree, as, for example, a hospital constructed like the Manhattan Hotel in New York, where everything is of non-combustible material. The floors and windows could be made of even less combustible material, I am sure. Dr. Ochsner puts aside the pavilion hospital, but such a building as he describes is practically one of superimposed pavilions, each floor representing a pavilion.

The gain which he makes in the way of sunlight and air by the elevation is manifest. It seems to me that there is a point which can be criticised and that is in the amount of plumbing. In one plan the bathrooms, etc., are in the two wings and the center of the building is quite free of any plumbing. In going through the hospital I was impressed with this same fact. I think if Dr. Ochsner is going to economize his nurses he must also economize his nurses' time. The amount of running to and from which a nurse would have to do in passing to and from the bathroom would be a considerable amount each day. In the construction of the children's hospital in San Francisco, I had to deal with an exceedingly obstinate architect. I had to calculate the steps between the bed which is farthest from the bathroom and found that the nurses walked two or three miles which could have been eliminated. The walks, of course, were broken, which is the only way they could stand it. With modern plumbing, such as you see in a modern hospital, which is absolutely perfect in its theoretical and mechanical construction, it would be possible to put in another bathroom which would answer admirably for the nurse. Then, too, surgeons are always washing their hands, and a nurse has to go and get the water every time it is needed. In other words, she has to go to so much trouble which is not necessary. Hot and cold water should be in every ward even if it contained only two beds. Another practical point is the heating of hospitals. We are using petroleum for fuel and it is exceedingly economical, the escaping steam being used for heating the building. Dr. Ochsner has put his operating-room at the top of the hospital and his kitchens should be the same place. Such a hospital as this, which should be very near the hotel center of the city so that hotel people could be transferred to it, should also have an annex in the country to which could be transferred such patients as have a long convalescence. Such a hospital in the center of the city offers good opportunities for the people who have a long convalescence and can not be moved to the country. The pure air of the country, the weather outlook and the opportunity to get out of doors, which is denied in the center of the city, is to be thought of. Any one building such a hospital as this should have weather plans and also include the country annex.

DR. E. W. CUSHING, Boston—I think that the author of this paper has rendered a great service. The work of Burnett, in England, and the example of the Johns Hopkins Hospital, in this country, seem to have remained as absolute standards of authority with architects and constructors of hospitals, although the theories as to the nature of infection and the knowledge of means to prevent it have greatly progressed since these works were written. I am interested in the planning of one of the great new hospitals of Boston, and I have been surprised to find how little has been written on hospital construction in the last ten years, or since the time when it was understood that infection of wounds was caused by actual contact of a solid or liquid medium rather than through the air, and since it has become possible to construct thoroughly fire-proof buildings. In large cities, where land is very valuable, it is evident that it is cheaper to build hospitals with less superficial area and higher than has been customary. With modern methods of heating and cooling and ventilating and with modern sanitary plumbing there seems no reason why a hospital should not occupy several of the upper stories of a lofty building in the heart of a great city. It is also true that in a hospital thus centralized in one building there are economies in heating and in the smaller distances to be traveled by nurses and others. It is not usually considered that extra steps for nurses mean a larger number of them and extra expense. It is certainly a great convenience for the visiting staff to have the hospital in a convenient place, and the same may be said in regard to the friends and relatives of the patients.

Nevertheless, for large general hospitals there are greater advantages in having plenty of land, so that there can be grounds for the ambulant and convalescent patients, and, although surgical infection may be usually carried by physical contact with an infected body, yet when the hospital gets crowded there are times in the best of hospitals when the wounds do not do well, even with all the refinements of modern

technic. We can not deny that in medical diseases the atmosphere is sometimes a carrier of infection, and when it comes to a large hospital with all sorts of diseases, including offensive cases, and with provision to make for a pathologic department, an autopsy room, etc., there will always be great advantages in locating the hospital in a suburb and on a hill, with plenty of land to allow for separate buildings for various purposes and to permit of future growth of the institution.

DR. GEO. W. CRILE, Cleveland—Dr. Ochsner has opened an important field for discussion. So far as the principles he lays down are concerned there is little to be said. While his system is to my mind almost perfect there are one or two points that occurred to me might be open for discussion. If a hospital is a teaching hospital then I think it is better, for obvious reasons, to have the pathologic building isolated. It would seem difficult to secure satisfactory isolation by this plan of construction. The pathologic pavilion should also be of considerable size. It is desirable to have the storehouse, kitchens, etc., in a separate pavilion. The plan of construction outlined is probably the best available if economy must be practiced.

DR. OCHSNER, in closing—I gladly indorse all of Dr. Sherman's points. It is intended that this hospital should be located in the residence portion of the city, away from the noise and smoke. The idea of having a separate annex at some distance from the city is a good one for patients who have only to be seen by the attending physician once or twice a week. The matters of heating and ventilation are carefully discussed in the paper. The kitchen is on the top of the building, entirely separated from the rest of the house, and the cooling rooms are also on the top. There are two recovery wards for patients after anesthesia. A small isolation room for dying patients has been provided for on each floor, and isolation wards for scarlet fever, erysipelas, diphtheria and other contagious diseases are provided for at a distance in a separate building. I believe that when there is an epidemic of supuration in cases which should heal primarily, a condition which Dr. Cushing has mentioned, it is not necessary to separate the cases because the cause of this is always found in some particular person, either a nurse or an assistant or the surgeon himself, who has been careless, and as soon as the error is corrected the suppuration ceases to occur in future cases. I believe a hospital of this size is very badly constructed unless it has a large garden, and we should not permit any one to build a hospital unless they provide such a garden. Dr. Crile's remarks concerning the location of pathologic laboratories are quite in accordance with my views on this subject.

DEATH DUE TO X-RAY?

MAURICE RUBEL, M.D.

HOUSE OFFICER, JOHNS HOPKINS HOSPITAL.
BALTIMORE.

NARRATION OF THE CASE.

History.—Sept. 9, 1901, Miss X. (aged 47) was admitted to Dr. Kelly's service, complaining of "pain in the left side, frequent micturition, general weakness and fever." Her family history was unimportant. The chief features of interest in her past history were that three years ago, after the fatigue following her attendance on a sick sister, she was seized with severe pain in the left side of the abdomen. Within a year this pain disappeared, but returned after an attack of grip, two years ago. Her physician at this time discovered both stomach and intestinal trouble, and the patient was treated by gastric lavage and by enemata. During this time she suffered from pain in the left side and back and from constipation and nausea at times, but never from vomiting. Ten days previous to her admission she had a chill followed by fever, and one week later she had a second rigor.

Physical Examination.—On examination the thoracic organs were apparently in good condition. The abdomen appeared normal in every way and nothing was made out on palpation or percussion, although it must be admitted that a satisfactory investigation of the viscera was not possible owing to the rigidity of the abdominal wall. Inspection of the genitalia

revealed the presence of abscesses of Skene's ducts and of urethritis.

September 10 the pelvic organs were examined under ether and found normal. No masses were palpated in either kidney region. The left ureter was catheterized with a wax-tipped catheter, but on its withdrawal no scratch marks were discernible. As the eye of the catheter was occluded, urine was not collected from this kidney.

Urine, however, taken from the bladder, was acid in reaction, contained no sugar, but revealed a considerable amount of albumin. On standing, there was a heavy white precipitate composed of epithelial cells, hyaline and finally granular casts and numerous leucocytes.

The patient's temperature was normal. She was discharged from the hospital, but came to the dispensary for treatment.

Treatment.—The urethritis and abscesses of Skene's ducts yielded to treatment, the urine became normal, and the patient was relieved of frequency of micturition, but the pain in the left side persisted. The symptom-complex of pain in the left side and back, associated with nausea and chills, suggested the probability that there existed a stone in the pelvis of the kidney, which the wax-tipped catheter had failed to reveal.

Skiagraph Taken.—Accordingly, a skiagraph was taken October 8. Two exposures, each lasting twenty minutes, were made. A Leed's coil was used—spark 3 inches—and tube was 16 inches from plate, about 6 inches from abdominal wall. The picture threw no light on the case.

Dermatitis.—About four days later, according to the patient, little papules appeared over an area one-half the size of the hand, just above and to the left of the umbilicus, where there was intense itching and burning. In the course of three weeks the skin over the entire abdomen became dry and assumed a purplish-red color. Soon "blisters" about three-quarters of an inch in diameter appeared. These broke and discharged a thick, yellowish material. Up to this time boric or zinc ointment had been used as a dressing. But as the patient could not receive the proper attention at her home she was again brought to the hospital, November 17. It was at this time that she first came under my observation. On examination the patient was seen to be well nourished. Her mucous membranes were of a fair color, tongue slightly coated. Lungs and heart negative. Blood was normal. No eosinophilia or leucocytosis.

Description of the Skin Lesion.—Abdomen was full, rounded and normal-looking in contour. Owing to the presence of the lesion about to be described, palpation was impossible. Quoting my notes taken at the time of admission: "Located on the center of the abdomen there is an area about 13 by 20 cm. in diameter, which is red and raw and completely denuded of epidermis. It is bathed with a thin, greenish-yellow discharge, which is apparently very irritating to the surrounding skin. On close inspection, one sees four distinct areas, which stand out from the denuded weeping surface on account of being somewhat paler and slightly elevated. Their outlines are indefinite, but their dimensions are apparently $2\frac{1}{2}$ to 3 cm. long by 1 cm. wide. These lesions, the patient claims, are scars, the result of counter-irritants applied in early childhood. The entire area is extremely tender to the touch, the slightest pressure causing excruciating pain.

"The epidermis immediately bordering this denuded patch is pale and macerated and lifeless in appearance. The entire abdomen beyond has a dark-brown color and the skin is thick and brawny, as far as the ensiform above, the pubes below, and laterally, it extends well into the flanks. (See cut.) The pubic hairs are almost entirely wanting."

Symptoms.—The chief symptoms complained of were "burning" in the wound and itching in the surrounding skin. The flanks seemed to be particularly painful and the right inguinal region was the seat of distressing pain, which was described as sharp and cutting in character.

Treatment and Course of Lesion.—Compresses of the filtrate from an admixture of lead acetate and alum in water were applied, and a 2 per cent. salicylic ointment was spread over the surrounding indurated skin surface. The painful area in

the flanks were treated by various counter-irritants. Under this treatment the epidermis grew in rapidly from the surrounding edges. The unevenness of the healing process gave the advancing epidermis at the periphery of the wound a pinked appearance. Just inside the white scarf-skin and bordering it all around the wound, in a band 2 mm. wide, the dark red, shiny, advancing epidermal growth could be seen.

So quickly did the new skin form that by December 7, about three weeks after admission, an area only 12 by 9 cm., and triangular in shape still remained unhealed. But now the process took a turn, the cicatrices before described broke down and formed ulcers which enlarged and undermined the skin and finally united, so that eventually there were one large ulcer and two smaller ones, the whole area covering a surface 14 by 14 cm. but still triangular in outline. The ulcers were about 3 mm. deep and covered with necrotic tissue, which was cleared away from time to time with salicylic acid. Under suitable treatment the ulcers granulated well, but there was absolutely no tendency for the epidermis to spread over the granulated surface, and on July 31, as there had been absolutely no improvement for two weeks or more, the ulcerated area was excised and skin grafted, but the grafting was not successful.

Patient's General Condition.—With regard to the patient's general condition since her admission, there is a great deal of

interest. From the beginning she was nervous and apparently weak, although she bore her suffering remarkably well. Her mental condition at times caused anxiety, for on several occasions she was very despondent and melancholia was feared.

Gastrointestinal Symptoms.—The chief difficulties in the treatment of the case and the most distressing features were associated with the symptoms referable to the gastrointestinal tract. Soon after the patient's admission to the hospital it was discovered that her constipation would not yield to ordinary treatment and that the ordinary laxatives were useless. She was given increasing doses of purgatives, and

powerful medication along with enemata, but our efforts were without result until the thirteenth day. The patient then experienced some abdominal discomfort and nausea, but no movements occurring every other day, but only

Dr. H. M. Smith, the employment of enemata and the use of drugs. On November 12, the bowels became again inactive and were applied to hospital. The patient became nauseated and vomited, for example, a hospital of bile-stained fluid. Examination of the in New York, where it was negative. All nourishment was discontinued. The floors and windows. Nutrient enemata were given and the material, I am sure. Dr. Oudin, Barthelémy and Darier, in their most admirable papers, review many cases that complained of nausea and vomiting after x-ray exposure. In Case 43

lost weight and strength, became depressed, and her condition was indeed serious. She had no stool now for practically twenty-two days, except that occasionally the enemata would come away slightly colored and flecked. Her gastric condition would not permit the administration of purgatives, and these (including croton oil), experience had taught were ineffectual. The only hope lay in moving the bowels. Hypodermics of atropia and strychnia proved useless; abdominal massage, owing to the ulceration of the wall, could only be partially practiced. But all efforts were unsuccessful until January 3, when there were three copious stools, and the bowels moved three to four times daily until the 12th. The patient recuperated rapidly, she became brighter, her pulse, which had risen to 140 to the minute (although her temperature was normal) fell to 110 and thereabouts. Her vomiting ceased and she again took food by mouth. Now that the bowels were again open, we took all measures to endeavor to keep them regular, but on the 12th of the month a repetition of the attack of vomiting, depression, high pulse (150) and constipation occurred and the patient was considerably worse than in the previous attack. For twelve days this persisted, when, for some unaccountable reason, the patient again had several copious movements, and as before she rapidly improved and took nourishment by mouth.

Operation.—It was at this time that the abdominal wound was at a standstill, and it was thought that the sooner the patient could be relieved of her suffering from the ulcer and the sooner she could get about the better would be her chance for recovery, for she certainly could not endure the strain of many more such attacks; and, as previously related, the ulcer was excised and skin grafted.

The patient recovered rapidly from the anesthesia and had far less nausea and vomiting than was expected in view of her condition. Within three days after the operation her bowels were moved and the nausea and vomiting ceased. Nourishment, which up to this time had been given per rectum, was now taken by mouth and retained. In fact, after the third day there was no nausea and there were copious bowel movements daily. In spite of the seeming improvement the patient became progressively weaker. At times during the night she was irrational, her pulse was of good volume and tension, but ranged between 120 and 140. Her temperature was irregular, reaching 100.5 on the second and fifth days after operation, and 101.7 on the ninth day. She lost rapidly in weight and strength. On the eighth day her mouth and tongue became ulcerated and soon were so tender that food, not even liquids, could be taken. Local treatment was of no avail. The patient steadily grew worse and died on the twelfth day after operation. An autopsy was not granted.

THE CAUSE OF DEATH UNDETERMINED.

What was the cause of death? Whether or not death was due to the x-ray could not, of course, be definitely settled without a section. It is most probable that the patient had some intra-abdominal trouble which we were unable to determine. On the other hand, the peculiar symptom-complex makes it appear as though the Roentgen ray may have produced some tissue changes of which we are totally ignorant. It seems probable that aside from the pathologic lesions produced in the nerves and vessels of the abdominal wall that similar injury may be wrought on the sympathetic system. The instances cited in which the prolonged use of the x-ray on the abdomen causes nausea and even vomiting plainly indicate that some obscure changes take place. In the cases in which the untoward effects are temporary, it is most rational to believe that there is no demonstrable pathologic process, but that merely a functional disorder of the internal organs exists.

CASES REPORTED IN LITERATURE.

Oudin, Barthelémy and Darier,¹ in their most admirable papers, review many cases that complained of nausea and vomiting after x-ray exposure. In Case 43

of their series, abdominal pain persisted for two months after a 45-minute exposure, but physical examination was entirely negative.

While the literature teems with recitals of cases of severe x-ray burns, there are extremely few references made to death following the use of the Roentgen ray. The few cases reported are incompletely given. I will give résumés of these cases.

CASE 1.—A man² in St. Paul met with a street car accident, and a skiagraph was taken. He has since died, and certificate of death attributes the unfortunate result to burns inflicted by the rays. The medical man who took the skiagraph denies that the patient was "burned so seriously as to cause fatal injury."

Here nothing is said as to the region of the body injured, extent of injury, time of death after the accident—in fact, none of the data necessary to the proper adjudgment of the case.

CASE 2.—Patient,³ female. Neck of femur was fractured and skiagraph taken April 7. Exposure lasted 2 hours. On April 27, a second picture was taken, with 2 hours and 10 minutes' exposure. Later the patient became mentally unbalanced, and the abdominal wall ulcerated, and she eventually succumbed. No further data are given, although death is attributed to the x-ray.

CASE 3.—In this case⁴, too, there was a fracture of the femur. Two exposures to the rays were made, twenty days apart. The first lasted 35 and the second 45 minutes. A 10-inch coil was used and 5½-inch spark. Eight days after the last exposure a "gangrenous slough" 6 by 3 inches formed on the abdomen. Death occurred six months later, and was attributed to "shock, as a result of fracture of the thigh and to the x-ray."

CONCLUSIONS.

From these few cases so meagerly reported one can not arrive at any conclusion. It is certain that in the literature there is no authentic case of death directly due to and following the use of the x-rays. All of the three cases had sustained an accident, and it is quite probable that death was directly or indirectly due to these injuries and that the Roentgen ray had nothing whatsoever to do with it.

Our case, it seems to me, is quite different from those cited. In the first place, there had been no accident and the patient was in a fairly good general condition before the burn occurred. That she gradually and steadily declined after the appearance of the abdominal lesion, there is no doubt. Whether this progressive decline, with the concomitant gastrointestinal symptoms, was due to internal tissue injury following the use of the x-ray, or whether it was the manifestation of some organic trouble, is very difficult to say. That the case was a very peculiar one is certain. I have reported it in the hope that if they exist it may bring reports of similar cases to press, and with the intention of bringing before skiagraphers the possible serious results that may be attributed to the use of the x-ray.

The progress of cremation in this country leads that of the entire world. There are twice as many incinerations in the United States as in all of the rest of the world combined. The number everywhere, however, is rapidly increasing. Spain is one of the last to recognize cremation. Russia will do so in the very near future.—*Meyer Bros.' Druggist*.

BINOCULAR MAGNIFIER FOR USE IN OPERATING.*

EDWARD JACKSON, M.D.
DENVER.

In using the binocular magnifier it is essential that the two lenses shall be kept the same height before the two eyes. Unless this is done binocular vision becomes impossible because of the vertical prismatic effect. To insure the keeping of the lenses in proper position the gutta-percha headband has been adopted to support the instrument. When this is obtained of the proper size softened by heat and molded to the head of the operator who is to use it, an ideal means of support has been secured.

To enable the operator to illuminate the field of operation and still keep both hands free for the operation, I have added a mirror to the instrument. This is illustrated in the accompanying cut.

Magnifier with illuminating mirror.

The condensing mirror of proper size and curvature gives as good lighting as the condensing lens ordinarily used for purposes of focal illumination. With it the source of light may be placed behind the patient or in whatever position may be most convenient. After the mirror has been properly adjusted, a very slight movement of the head will give any modification of illumination that may be desirable; and, without an assistant, both hands are left entirely free for use in the operation.

The instrument is of great practical service in such minor surgery as the removal of misplaced lashes, or of foreign bodies embedded in the cornea; as well as in more serious operations, like the division of the capsule for secondary cataract.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, H. V. Würdemann and J. A. Lippincott.

Treatment of Ulcers of the Leg.—Chenoweth recommends in *Med. Record* the following: "In ulcers not larger than a dollar I have the patient put the leg in hot water for an hour, then wash with soap and clean water, dry the leg, then wash with a weak formaldehyd solution, dry thoroughly and dust ulcer with boracic acid. Now I take strips of rubber adhesive plaster one-half inch wide, commence back of the toes, and apply tight, overlapping each lower strip, up to the knee, then apply an ordinary roller bandage. I allow this dressing to remain until the discharge shows through, which it will do in from five to seven days, and then the whole dressing is taken off and the ulcer cleansed as before, and a clean dressing applied. This will usually remain for about two weeks, when it is removed and the wound dressed as before. These ulcers are generally well in six weeks' time. In cases in which the ulcers are larger than a dollar, I send the patient to bed for two weeks with instructions not to get up except to empty the bowels and bladder. While in bed I have the patient use a moist dressing of one ounce of boracic acid to one quart of water. Unless the ulcer is very large, the two weeks' rest will reduce it so that it can then be treated as a small ulcer, but if two weeks is not long enough I keep the patient in bed two weeks longer, although this is very rarely required. As soon as the plasters are applied I allow the patient to follow his usual occupation. After the ulcer has entirely healed I have the patient wear an elastic stocking."

SATURDAY, NOVEMBER 22, 1902.

THE BACTERIOLOGY OF EMPYEMA AND ITS BEARING ON SURGICAL TREATMENT.

Even in these enlightened days the truth that empyema is a surgical disease is not as generally recognized as it should be. The fact that a few patients have recovered after simple aspiration of purulent effusions from the pleura has apparently encouraged many physicians to wait for some time and try medical measures before deciding on operative measures. The belief seems quite general that certain purulent effusions, for example, those following pneumonia, are more likely to disappear spontaneously than are those in which some other organism is present.

Some ground for this is found in one of the first careful studies of the bacteriology of pleural exudates by Prince Ludwig Ferdinand¹ of Bavaria, who found that infections with pneumococcus run a much milder course than do those by the streptococcus, for example, and reported several spontaneous recoveries in pneumococcus empyema. Bearing on this subject the study of 135 cases of empyema treated at the Boston City Hospital during the past six years, which is reported by Withington,² is of interest. The bacteriologic examinations in this series of cases were in charge of Professor Councilman. Pneumonia preceded the empyema in the great majority of cases; 80 certainly out of 135 and probably 95 cases were preceded by this disease. The period after the onset of pneumonia when pus was first detected ranged from six to sixty-six days, and averaged twenty-five days. In spite of the fact that most of the cases followed pneumonia it seems that the *Diplococcus lanceolatus* has no distinct relation with the condition, for other organisms, specially the streptococcus, were quite as frequently present. In all the pneumococcus appeared in 60 cases and the streptococcus in 74 cases. In a number of these cases the infection was a mixed one; staphylococci, the colon bacillus, the typhoid bacillus and several others being represented in the series. Operations were performed in all but 20 cases. Of the 20 cases not operated on several seemed to be recovering, and while the exudate contained pathogenic organisms it was not markedly purulent and operation did not seem to be necessary. In other cases operation was refused. The operation performed most frequently was drainage of the pleura by incision after resection of the seventh or eighth rib. The immediate effect of operation was

to reduce the temperature and improve the general condition of the patients so that 92 left the hospital improved after an average stay of about thirty-two days. The majority of these patients were well on the way to convalescence.

From a surgical standpoint a very interesting fact brought out in these cases is that the gravity of cases with streptococcus infection does not seem to have been greater than those from infection with the pneumococcus. This is contrary to the observations of Prince Ludwig Ferdinand and several observers since the appearance of his article. On the whole, the mixed infections appeared to be more fatal than those of a single organism. Although 10 patients out of 20 in this series of 135 recovered without operation, the cases seem to have been for the most part those in which the effusion was not very definitely purulent; and even including these favorable cases, the mortality was 50 per cent., while in the cases operated on, which included some very grave cases accompanied by such conditions as abscess or gangrene of the lung, septic infections and other diseases elsewhere, the mortality was only 29 per cent. This mortality is, we believe, very much higher than after operation in ordinary uncomplicated cases of empyema. Withington states that some cases certainly recover without operation, but it is difficult to determine in advance which these will be.

It seems reasonable to conclude from this paper and from other recent observations, that whatever may be the infection operation promises the better chance for recovery. A possible exception is found in the rare cases of infection by the typhoid bacillus. Gerhardt³ reports a case in which a purulent exudate containing typhoid bacilli absorbed spontaneously, and from a careful study of the literature of the subject he finds seven other cases of infection by typhoid bacilli with recovery after simple aspiration. The cases of purulent effusion in the pleural cavity in which it is not possible to determine by reliable bacteriologic examination that the infection is with the typhoid bacillus should certainly come to early operation. If this treatment were generally adopted many lives would be saved and the extensive operations which have been devised by Estlander and Schede would be entirely unnecessary.

TYPHOID FEVER IN YOUNG CHILDREN.

About a year ago¹ we directed attention to the fact that evidence was accumulating tending to show that typhoid fever was not so rare in children as had been generally supposed. This has been still further substantiated by observations more recently published. At the last annual meeting of the American Pediatric Society the reading of papers on typhoid fever in children was followed by considerable discussion as to whether this disease ever occurs in children under two years of age.

3. *Mitteilungen aus den Grenzgebieten der Medizin und Chirurgie*, 1900, v, p. 103.

1. THE JOURNAL A. M. A., Dec. 21, 1901, p. 1681.

1. Arch. f. klin. Med., 1892, vol. 1, p. 1.

2. Boston Medical and Surgical Journal, 1902, vol. cxlvii, p. 505.

The writer of one of the papers had collected 37 or 38 cases of typhoid fever which had been reported in children under two years of age, in most of which the diagnosis was founded on the clinical symptoms, and in only about one-fifth of which the typhoid bacillus had been isolated. In the discussion several clinicians of extensive experience stated that they were not certain of having ever seen typhoid fever in infants of less than two years, and one observer, with extensive pathologic experience, stated that in the New York Foundling Asylum no case had occurred in his experience of ten years, nor in the experience of one of his colleagues in twenty years. In another place he has said that in 2,000 autopsies in the same institution there was no case with the lesions of typhoid fever. Later investigations have confirmed the opinion of those who recognized certain febrile diseases in infants as typhoid fever.

The former belief that typhoid fever must be accompanied by the usual intestinal lesions has been found to be unfounded. It is now known that infection with the typhoid bacillus may occur, the typhoid bacillus being in the blood, while the intestinal lesions are slight or absent. In such cases the diagnosis is made certain by Widal's reaction and the cultivation of the bacilli from the blood. Because of the slight development of the intestinal lesions in children as compared with adults, it was not unnatural that those who saw so little at the postmortem to correspond with their ideas of typhoid fever should have become skeptical as to whether the disease ever occurred at early ages. On the other hand, those observers who were less impressed with the pathologic anatomy, and depended on the clinical symptoms, were led to diagnosticate certain cases as typhoid fever by a process of exclusion. That typhoid fever is not actually very rare under the age of two and one-half years is again emphasized by the cases recently collected by Griffith and Ostheimer.² They have brought together 325 cases from the literature and from their personal observation. From the imperfect information in many of these cases as to the presence or absence of Widal's reaction, it is impossible to judge of its value as a diagnostic measure. It is generally believed that Widal's test is not as valuable in children as in adults; however, it seems to give positive information in a large proportion of cases, as Hand and Walker³ obtained a positive reaction in over 87 per cent. of cases, and Abt⁴ in all but two of 200 cases.

THE SURRENDER OF EDDYISM.

The latest revelation of the "profitess" of Eddyism is in effect that the public mind has not yet reached the point where Eddyite practice can control infectious diseases. Therefore, the diplomaed output of the rapid process, \$300 courses of lectures, are not to attempt any more to cure such disorders by present or absent treat-

ment. One or two recent experiences of her followers, with possible legal proceedings in prospect, may have had something to do with this latest pronouncement, but whatever the cause, it is a confession of failure and—what is still better—a chance for life for many of her deluded followers. We shall never know how many human lives have been sacrificed by Eddyism, Dowieism, etc., to say nothing of the needless disease and suffering they have caused. The same announcement authorizes and advises the reporting of contagious diseases to the proper authorities, Mrs. Eddy, or the literary syndicate of Eddyism—a great scheme, by the way—having at last interpreted the Scripture injunction to "render unto Cæsar the things that are Cæsar's" as applying to this point. It would have been better for the public if she had done this earlier, but it is well that it is done now.

It can not undo the mischief that has been done, nor is it an absolute assurance against mischief in the future. The ablest physician is not always able to certainly diagnose dangerous communicable disorders in their beginnings, but he can advise precautions while reserving his opinion. Is the Eddyite healer to be expected to be a better diagnostician or to have the modesty to refrain from meddling where he or she is—by this confession of the "profitess"—incompetent? We fear not, and there may be future tragedies as sad as those that have stirred the public in the past. It is, moreover, not in contagious or infectious diseases alone that this possibility exists; we have all heard of cases of neglected injuries, retained placenta, etc., that the most ordinary general practitioner would not have neglected, go on to fatal septicemia in Eddyite hands. Who can tell the countless hours of needless suffering and the massacres of the innocents that this Moloch has caused, and will yet cause, unless the high-charging C. S. D.'s diplomaed by Mrs. Eddy and her syndicate have the self-denial to forego their lucrative perquisites? Is there any good reason to believe that they will recognize contagion in time to prevent its spread or that the public ought to trust them to foresee the dangers that can only be properly guarded against by the earliest possible recognition? As the *New York Herald* says, the only possible safeguard for the individual and the public is to "insist that no Christian Scientist shall treat any patient unless the exact nature of the ailment has been determined, either by a competent physician or by a local health official."

There is still another aspect of this latest revelation that we can also properly notice. The whole Eddyite cult is wrapped up in its healing claims that are indicated in the title of its sacred book, "Science and Health." With the latest pronouncement the greater part of these are sacrificed at one sweep, for with the advance in medical science the list of communicable diseases is increasing daily and includes nearly all the commoner serious disorders. The range of Eddyite treatment is thus seen to be pretty seriously limited, but the most damaging effect would be naturally expected to be

2. Amer. Jour. Med. Sci., November, 1902, p. 868.

4. Chicago Med. Recorder, Oct. 15, 1902, p. 252.

on the faith itself of its followers. As a clergyman, commenting on Mrs. Eddy's order, says:

"This, then, is the comfort given to multitudes of followers who have made an offering of lives more precious than their own, that they might be faithful to Mary Baker Eddy's teaching. Under her directions mothers and fathers have refused to permit a doctor to attend their children, and have seen them die rather than depart from the teaching that there is no infectious or contagious disease. Now they are told that there are such diseases."

Let us hope that this is the beginning of the end of the Eddyite delusion.

A HIGHER STANDARD OF ENTRANCE TO OHIO MEDICAL SCHOOLS.

The Ohio State Board of Medical Registration and Examination has still further raised the standard of minimum requirements for entrance into the medical schools of that state. At least two years of preliminary Latin study are now required and the examination includes botany or zoology, physics and chemistry as well as rather more advanced mathematics. The requirements are still none too high, but are a marked advance that it would be well if other boards could imitate. The inclusion of a certain amount of Latin study is judicious, for, say what we will, it is the best foundation for the scientific study of medicine, and though the requirements may not go far enough to insure very much classical culture, it is a step in the right direction. We are not likely to be altogether the gainers by the popular tendency of the day to reject the old courses of classical study as a leading part of an education, not even in a practical way. The graduates of the German gymnasia where the classics are taught are found to be on the whole better fitted for the later scientific courses than are those of the *Realschulen*, where the studies are more directly in the modern practical lines.

It is fortunate that the Ohio law has put into the hands of the registration board the power to regulate the preliminary requirements of the medical schools of the state. The latter may suffer for a time, and some have already succumbed, and others may, but the final result will be that an Ohio diploma will be of so much the more worth. It will be well if in future amendments to the medical practice acts similar provisions are adopted in other states and so drawn up that the standards can be raised to meet the requirements of the times, and the preliminary examinations taken, as in Ohio, entirely out of the hands of the medical schools themselves. At present there is little danger of the standard being made too high; medicine is classed as a learned profession and we should endeavor to make it more deserving of the name than it has been in the past. With all our facilities for education, free schools, high schools and universities practically free, there is no reason why any aspirant for the

medical profession should not be better prepared than is the rule at present.

It is not to be expected that any new methods will be perfect from the first, and the present defects in the Ohio system, the lack of uniformity of examinations by the different examiners, for example are only the temporary imperfections of a new machine that will be remedied by time and use. We hope there will be no backward steps and we do not fear any too enthusiastic rushing to extremes, but look to the Ohio plan—we do not call it an experiment—as one that will soon have to be generally adopted, with such modifications as experience and progress may require.

AN INDEX OF AMERICAN MEN OF SCIENCE.

Prof. J. M. Cattell of Garrison-on-Hudson, N. Y., who is compiling a biographical index of scientific men of the United States for the Carnegie Institution, asks in the November 7 issue of *Science*, for aid in that work. There are many, he says, in private life, not members of scientific societies, who have published research work of value, and he will be glad to have their names and addresses. The research work referred to must, of course, be purely scientific, but there are many medical men who have done such and the names of some of them may have escaped Professor Cattell's search. If this meets the eye of any of those who have not received his circular they will do well to inform him, giving a list or statement of their publications with their addresses so as to be duly included in the index. It will probably be ultimately published and be the standard reference authority for the names of living American men of science.

NEW YORK HOSPITAL PHYSICIANS AS PAUPERS.

The arrest in New York City, November 4, of the superintendent of the Willard Parker Hospital for Contagious Diseases, five physicians and two attendants attached to the institution, on the charge of illegal voting, was for an ingenious reason. According to the *New York Medical Journal*, "no question was raised as to the good faith of the prisoners, the point being taken by the prosecution that under the law physicians resident in hospitals who receive compensation from the city are classed as paupers and not entitled to vote." This astonishing state of affairs leads one to suspect political intrigue, rather than to believe the law to exist as stated. Anywhere but New York this would be taken as an unusually daring piece of political bluff. Our contemporary, however, is alarmed, and such phrases as "inviolable rights," "liberty is infringed upon," "deplorable tendency" and "government become a despotism" punctuate the editorial. It would be a serious matter if such disfranchisement were the lot of every city-paid physician, but it certainly need not be. If there prove to be any obstacle in the way of New York public hospital physicians, to prevent their voting, their confrères are surely able to secure its removal and to rescue these unfortunate physicians from the ranks of paupers. Why should city-paid physicians be classed as paupers any more than the city-paid mayor and police?

A NEWSPAPER FOR THE NERVOUS.

According to a cable despatch from Vienna, a newspaper for nervous persons is projected, which will handle startling occurrences in such an unexciting way as to permit sensitive individuals to keep *au courant* with the times without the needless shock liable to be produced by usual chronicles. It will be a demulcent of the day's doings, rendering them palatable to the weakest stomach. There are some perhaps who would say that we have such periodicals now, but that is intended as a slur, and not to be taken seriously. In this new organ, scare-heads, we suppose, will be tabooed, all the bad news will be broken gently, a general mild neutrality preserved on all irritating and disputed questions, wars and rumors of wars will be treated most diplomatically and all uncomfortable details of catastrophes, bank failures, etc., be scrupulously avoided. In this way the restful and unirritating environment so needed by many patients will not be broken in upon while at the same time they will not forego altogether the pleasures of enlightenment as to the world's progress. The worst thing about it, however, is the possibility of suggestion; a partial concealment or revelation is often the strongest stimulant to the imagination. The eminent usefulness of the de-horrorized and expurgated chronicle has its possible hindrances, but we wish it success.

THE LICENSING OF PROFESSOR LORENZ.

We have commended¹ the action of the Illinois State Board of Health in following the dictates of the law in requiring Dr. Lorenz of Vienna to take out a license to practice in the state. The board exercised the leniency that the law allows in not making him take a full examination and the whole process was over in an hour. This deference was a courteous action, since there was no question as to his fitness to receive a license. A Southern contemporary,² however, has the following to say: "Too great censure can not be heaped upon this board for its action in this matter." We regret to see such an anarchistic tendency in the medical press. The disregard of law is sufficiently in evidence in the land not to need encouragement from the profession. The editorial quoted says further: "Professor Lorenz acted with dignity throughout, but it is not agreeable to think what opinion of America he will take back with him." He will think better of America than would have been the case had he been allowed to practice unlicensed. American lawlessness has approached too near to the status of a byword abroad to be comfortable. Dr. Lorenz knows what would happen to an American surgeon attempting unlicensed practice in Austria. After the Professor's license had been granted here he expressed himself as not offended by the requirement and said that it was entirely proper.

WHY PROHIBITION FAILS.

The *Journal of Medicine and Science*, the official organ of the Maine Academy of Medicine and Science, and the only regular medical journal published in the state, says that prohibition does prohibit if there are

only zealous and faithful officials to enforce the law. That the law can be enforced was shown, it says, by the late sheriff of Cumberland County, and a noticeable diminution in the demands on the poor fund was an accompanying result. It quotes, further, the experience of the city of Quincy, Mass., which for twenty years has been without the open saloon. During that time it has doubled its population, tripled its valuation and increased its savings bank deposits over fourfold. All this is not so remarkable as the additional fact that while the population has doubled, the amount required for poor relief has diminished a notable per cent. This is testimony from an apparently competent witness on the ground and it must be accepted until rebutted by better. It is undeniable that we can not absolutely prevent illegal liquor selling by law any more than we can robbery and murder or less criminal acts, but this truth does not warrant the commonly repeated assertion that "prohibition does not prohibit" in the sense that it can not successfully prohibit. The trouble seems to be rather that we can not or will not often enough elect officers who, sworn to enforce the laws, will not perjure themselves. That any community is better off without the free and open sale of liquor needs no argument; it is to physicians at least an established fact that has no relations with the academic question of the consumption of alcohol in the healthy organism or that of its occasional value as a medicine in pathologic states. It is simply a question of appetite, and appetite rules, unfortunately, too much.

AN AMBITIOUS AUTHOR.

One of the most presumptuous proceedings on the part of an individual in getting a production published in a large number of medical journals is that of a Brooklyn physician. This gentleman sent us an article, which was ostensibly a protest against the use of the curette,¹ and advocating the use of an "alkaline solution." The article was neither good nor bad, just an ordinary paper, repeating old arguments and advocating nothing new. Neither did it appear to be an advertisement of anything, unless the "properly combined alkaline solution" recommended has reference to some proprietary medicine. This is possible, and if so the article would have been followed up in such a manner that there would be no misunderstanding as to what is referred to. We say "would have been," for the probability is that if there was anything of the kind intended the manufacturers of the proprietary medicine referred to will hesitate now to take advantage of the first "coup." The MS. was returned by us, not because we suspected anything, nor because it was particularly inferior. Shortly after we returned it, it appeared on the same date in two of the weeklies, and another weekly brought it to our table the next week. Immediately afterward it began to appear in monthly journals of all kinds, including homeopathic. We have now had the pleasure of seeing this remarkable production in no less than twenty-two medical journals, and the journals and the article are still coming. We wrote to the editors of a number of the journals in which the article first appeared, asking if it was

1. THE JOURNAL, October 25, p. 1054.

2. The Louisville Monthly Journal of Medicine and Surgery, November.

1. Septicemia and the Curette. By H. Plympton, M.D., Brooklyn, N. Y.

understood by them to be an original contribution, and each gave the same reply: that it came with a request for immediate publication. Each editor supposed that it was contributed to his journal only. We may be mistaken in suspecting that the article was to be utilized in pushing a certain proprietary; it is barely possible that the author merely wished to advertise himself. If this is the case, he has succeeded magnificently. It is barely possible that he may find that he has overdone the thing, especially if he had proposed to publish articles in medical journals hereafter. It is extremely likely that he will realize that he may fool the editors once, but only once.

Medical News.

CALIFORNIA.

Riverside Hospital Opens.—The new Riverside City Hospital was opened for the reception of patients, October 27.

Hospital for State University.—The University of California is considering the advisability of erecting a \$400,000 hospital in San Francisco, to be under the complete control of the medical school.

Addition to County Hospital.—The county supervisors have decided to expend \$350,000 in the erection of six new buildings for the Los Angeles County Hospital. These will include an administration building, a power house, a kitchen building, and a contagious ward and two medical buildings.

Vital Statistics of San Francisco.—In October 606 deaths occurred, equivalent to an annual death rate of 20.19 per 1000. In October, 1901, there were 566 deaths, or an annual rate of 18.86. The principal causes of death were tuberculosis 73, cancer 37, diphtheria 23, heart disease 70, Bright's disease 28, accident 32, homicide 3, and suicide 17. During the month 500 births were recorded.

CONNECTICUT.

Personal.—Dr. William J. Tracey, for nearly twelve years health officer of Norwalk, has resigned, and Dr. Henry C. Sherer has been appointed in his stead.

Infectious Diseases.—During October there were reported to the State Board of Health 220 cases of scarlet fever, 175 of diphtheria, 148 of typhoid fever, 72 of whooping cough, 36 of measles, 15 of consumption, 6 of cerebrospinal fever and 4 of smallpox.

To Establish Tuberculosis Sanitarium.—The incorporation of the New Haven County Anti-Tuberculosis Association has been consummated to establish and maintain in New Haven County a sanitarium for the treatment of curable cases and to aid all efforts put forth for the suppression and prevention of the disease.

October Deaths.—There were 1133 deaths in the state during October. This was 33 less than in September, 71 more than in October of last year, and 31 more than the average number of deaths in October for the five years preceding. The death rate was 15.9 per 1000 per annum for the large towns, for the small towns 12.2, and for the whole state 14.9. The deaths reported from infectious diseases, including diarrheal, were 283, or nearly 25 per cent. of the total mortality.

ILLINOIS.

The Kewanee Public Hospital Association has been incorporated.

Zeller Received.—Dr. George A. Zeller, superintendent of the Illinois Asylum for the Incurable Insane, Bartonville, who has recently returned from the Philippine Islands, was tendered a reception at the asylum, November 5.

Illinois State Medical Society Change of Date.—In order to accommodate itself to the date of meeting of the American Medical Association, the Illinois State Medical Society has changed the date of its annual meeting in Chicago to April 29 and 30 and May 1 and 2, 1903.

Smallpox in Evanston.—Up to November 17, 57 cases of smallpox have been reported, all except 3 among foreigners. Vaccination and revaccination have been very generally practiced. The village has arranged to send such cases as it may desire to the Isolation Hospital, Chicago.

CHICAGO.

Alexian Brothers' Hospital Benefit.—The annual benefit concert for the Alexian Brothers' Hospital netted the institution about \$5000.

Pneumonia Causes Concern.—The increase in pneumonia is causing the Health Department great concern. They call attention to the wide distribution of the germ.

Increase in Mortality.—For the week ended November 1 the death rate was 12.56 per 1000 per annum; for the week ended November 8, 13.43, and for the week ended November 15, 13.91. Last week's 486 deaths represent an increase of 10.5 per cent. over the first week and of 12.6 per cent. over the corresponding week of last year.

Cottages for Consumptives.—The commission appointed a year ago by President Hanberg of the county board to devise plans for improving the service of the Dunning institutions, recommends the abandonment of the present consumption hospital and the construction of cottages for the treatment of the disease. The commission also recommends that the incurable insane patients be separated from those suffering from temporary dementia.

Personal.—Dr. Charles Louis Mix has been appointed to the medical staff of Cook County Hospital.—Dr. Jaques Loeb has been appointed professor of physiology in the University of California.—Dr. John R. Neely has been made acting superintendent of the Cook County institutions, Dunning, pending the appointment of a successor to Superintendent Lange.—Dr. and Mrs. Frank W. Jay returned to Chicago after a year's trip abroad.—Dr. Edward B. McDowell has returned from a trip to Fiji, Samoa and Hawaii.

LOUISIANA.

The Louisiana State Board of Health, November 12, 1902, elected the following officers: Dr. C. L. Horton, medical inspector; Dr. S. G. Gill, shipping inspector; Dr. P. E. Archinard, bacteriologist; Dr. J. H. Lamb, quarantine inspector at Port Eads; Col. F. C. Zacharie, attorney.

California Censured Again.—At a meeting of the State Board of Health, November 12, resolutions were adopted censuring the California Board of Health for suppressing facts in relation to bubonic plague in San Francisco, and recommending a national conference for the purpose of adopting measures to eradicate the disease.

Charity Hospital Staff.—At the regular monthly meeting of the Board of Administrators of the Charity Hospital of New Orleans, held November 3, Dr. J. A. Danna was elected second assistant house surgeon, vice Dr. J. M. Batchelor promoted to the position of first assistant house surgeon, which vacancy had been caused by the resignation of Dr. E. D. Fenner.

Arrangements for Medical Meetings in New Orleans.—The Committee on Arrangements' subcommittee on finance of the American Medical Association held a meeting at which plans were discussed as to means of raising funds to entertain the physicians expected to be in the city at the meeting of the Association in May next.—The committee of arrangements of the American Public Health Association, which will meet here, December 8, and be in session for five days, held a meeting November 12. An elaborate program of entertainment was decided on. Dr. Clement P. Wilkinson is chairman.—Arrangements are being made for entertaining the Association of Medical Officers of the Army and Navy of the Confederacy, which will meet in this city, April 19, 1903, at the time of the United Confederate Veterans' reunion.

MAINE.

Banquet to Dr. Hunt.—After twenty-eight years of faithful service as superintendent of the Maine General Hospital, Portland, Dr. Charles O. Hunt retired a short time ago. On November 5 Dr. Hunt was given a complimentary dinner by the past medical officers of the hospital.

Personal.—Dr. Charles D. Smith, Portland, has been appointed superintendent of the Maine General Hospital, Portland, vice Dr. Charles O. Hunt, resigned.—Dr. Samuel J. Bassford, after 21 years of practice in Biddeford, has retired.—Dr. Edson E. Goodrich, Waterville, has been appointed superintendent of the Oldtown Hospital, and has moved to Bangor.

Damages Against Physician.—In the Supreme Judicial Court, Augusta, November 8, Associate Justice William P. Whitehouse presiding, the jury in the case of Leonard Barber of Manchester vs. Dr. George C. Parker, Winthrop, returned

a verdict of \$241.42 for the plaintiff. The plaintiff claimed that the defendant treated a dislocation of the right shoulder in an unskilful and careless manner and prevented the plaintiff from attending to ordinary business and caused him much suffering. The defense contended that the case was treated properly. A number of leading physicians and surgeons of the state testified for the defense. A motion for a new trial was filed.

NEBRASKA.

Creighton Medical College, Omaha, opened for the year with 165 students, of whom 55 belong to the freshman class.

Medical Library Transferred.—The library of the State Medical Society, numbering about one thousand volumes, has been transferred to the Lincoln library.

Corporation Not a Practitioner.—A corporation can not collect money for services as a physician. So it was ruled by Judge Stubbs at Omaha November 15 in the case of the State Electro-Medical Institute against L. N. Platner. Suit was brought to recover \$75. Judgment was obtained in the justice courts. The case was appealed and the finding reversed, because, as a corporation can not practice medicine under the state laws, it can not collect for its services.

NEW YORK.

Smallpox in Rochester.—There are now 33 cases of smallpox at the Hope Hospital, Rochester, N. Y.

Death Rate of Large Cities.—Of the twelve cities of 5,000 population or more, Schenectady has the lowest annual death rate—12.3 per 1,000. Elmira has a death rate of 13; Syracuse, Buffalo and Rochester, 14; Albany, 15.2; New York, 7; Troy, 17.5; Binghamton, 18.5; Newburgh, 18.6; Auburn, 0, and Yonkers, 21.5.

Site for New State Hospital.—Members of the State Lunacy Commission spent a few days inspecting sites for the proposed new state hospital for northern New York. It has practically been determined that the new institution shall be located in Washington County. Comstock's, Smith's Basin, Ialem, Greenwich and Hartford were visited. The next legislature will be asked to make an appropriation for the new hospital.

Buffalo.

Unclean Barbers Convicted.—As a result of a concerted action by the health department inspectors and the union of the Buffalo barbers, eight Italian barbers were convicted in the municipal court of violating the city ordinances regulating the management of barber shops. The complaint in each case was that the barbers have been using one towel to every two or three customers, where the ordinance provides that each customer shall have a clean towel.

Comparative Mortality.—The last monthly statement issued by the Bureau of Vital Statistics shows 393 deaths in October as compared with 431 in October, 1901, a decrease of 38. Taking the death roll month by month since the first of the year and comparing it with the corresponding months last year it is found that there was a decrease in each month except March and April. The total for the ten months shows a decrease of 152 deaths from the number reported for the first ten months of last year.

New York City.

New Superintendent for Bellevue.—Dr. William Mabon, Ogdensburg, superintendent of the St. Lawrence State Hospital for the Insane, has been appointed Superintendent of Bellevue Hospital, New York.

Dr. Whitmore Arrested.—Dr. B. T. Whitmore, the eastern representative of Parke, Davis & Co., was arrested, last week, on the charge of obtaining money by extortion from the Water Front Improvement Company.

Health Officer Doty To Be Reappointed.—It is said that the governor has already decided to reappoint Dr. Alvah H. Doty health officer of the port of New York. Dr. Doty has served in that capacity since his appointment by Governor Morton in 1895.

Medical Laboratory Suit vs. New York University.—The Appellate Division of the Supreme Court has just handed down a judgment decreeing the return to the medical college laboratory of certain property held in trust by the New York University. The property, which is valued at \$150,000, was transferred to the university in 1897, but for several years there has been litigation over it, the contention being that the university has been guilty of a breach of trust.

Popular Lectures on Consumption.—As a part of the systematic campaign of education to be conducted by the Charity Organization Society, it has been decided to have monthly lectures on the nature of consumption and the means of preventing its spread delivered at night in the public schools. These lectures are to be in various languages so as to be understood by the denizens of the lower East Side. In connection with this announcement, the statement is made that more than 50 per cent. of the deaths among negroes in this city are due to tuberculosis.

Personal.—Dr. Frederick Holme Wiggin has been appointed visiting surgeon to the City Hospital.—Dr. Wisner R. Townsend has been appointed to the vacancy on the committee on union of the New York State Medical Association left by the election of Dr. Frederick Holme Wiggin as president of the association. Dr. Wiggin is a member ex-officio of this committee.—Drs. Guy Brewster and Gertrude Light, as a result of competitive examination, have been appointed sanitary inspectors.—Dr. H. Beckman Delatour has been appointed surgeon-in-chief of the ambulance service of Brooklyn.

New Hospital Island for Immigrants with Contagious Diseases.—President Lederle of the Board of Health announces that progress is being made in the plan to build a new island in New York Harbor between Ellis and Liberty islands on which to build a hospital for the care of immigrants suffering from contagious diseases. Last September President Lederle notified Commissioner Williams that the Department of Health would terminate the agreement by which the city cares for cases of contagious diseases among the immigrants at this port. The department will take care of these cases, however, until the Government has provided accommodations for them.

OHIO.

Dinner to Dr. Gallagher.—The Alumni Association of Ex-Internes of St. Alexis Hospital, Cleveland, gave a dinner November 6, in honor of its president, Dr. John V. Gallagher, who has recently returned from abroad.

Smallpox Diminishing.—For the week ended October 11, there were reported to the State Board of Health 84 cases in 21 locations in 18 counties; for the week ended October 18, there were 73 cases in 18 locations in 17 counties, and for the week ended October 25 there were 75 cases in 20 locations in 14 counties.

Personal.—Dr. Samuel C. Lindsay, late acting assistant-surgeon, U. S. Army, has returned from the Philippines to his home in Salineville.—Dr. Raymond C. Whalen will return from Manila and resume his practice in Youngstown, in February next.—Dr. Earl E. Gaver, Columbus, has been appointed assistant physician at the Columbus State Hospital for the Insane.

True Bills Returned.—In the cases of Drs. Charles F. Cooke and Asa E. Hoskinson, Columbus, whose licenses to practice were revoked by the State Board of Medical Registration and Examination, as noted in THE JOURNAL of October 7, the grand jury found indictments October 23, on the charge of having attempted a criminal operation on a young woman, who died later from sepsis. Both the accused were released on bonds.

Tuberculosis Commission Meets.—The State Tuberculosis Commission met in Columbus, November 10, and organized by electing Hon. Joseph H. Outhwaite president, and J. Warren Smith secretary. The other members present were Dr. Charles Slocum, Max Senior and S. S. Knabenshue. The commission discussed its duties in a general way and decided to present to the legislature papers on the following subjects:

"What Is Tuberculosis? Its Prevention and Curability, Including the Sanatoria Treatment," by Dr. Charles E. Slocum, Defiance.
"History and Records of Sanatoria, Both Foreign and Domestic, with Comparative Climatology Thereof," by Dr. George C. Ashmun, Cleveland.

"Economic Waste Resulting from Tuberculosis as Shown by Reports of Hospitals, Orphan Asylums, Jails, Charitable Associations and Fraternal Societies," by Mr. Max Senior.

"The Climate of Ohio as It Relates to the Location of Sanatoria," by Mr. J. Warren Smith.

"The Sanitarium: Size, Plans, Cost, Situation and Administration Expenses," by Mr. S. S. Knabenshue.

PENNSYLVANIA.

Internes Aggrieved.—Seven resident physicians of Mercer Hospital, Pittsburg, resigned, November 7, on account of dissatisfaction at the work required of them by the attending staff.

Smallpox at Erie.—There are a number of cases of smallpox at Erie. Dr. Chester Stranahan, one of the prominent physicians of the city, has been stricken with the disease.

State Hospital for Epileptics.—The Pennsylvania State Convention of the Directors of the Poor, at a recent meeting in Somerset, recommended the purchase of Highland Inn and 100 acres of land for the establishment of a state hospital for epileptics.

Examination of Judges for Retirement.—The last legislature passed an act authorizing the governor to appoint medical commissioners to inquire into the mental and physical condition of judges, with a view of having those incapacitated retire on half-pay for the remainder of their terms. Governor Stone proposes to go over the entire judicial list, and wherever he finds a judge who has not been able to perform his judicial functions for a year or more, he will appoint a commission to examine him and report the result. On such a commission the governor has appointed Drs. John V. Shoemaker, Philadelphia; Alexander G. Fell, Wilkesbarre, and William K. Dolan, Scranton.

Philadelphia.

The Mutter lecture on surgical pathology will be delivered at the College of Physicians, December 2, by Major Louis A. La Garde, surgeon, U. S. Army, on "Poisoned Wounds by the Implements of Warfare."

The Welch Reception.—On November 14 at the Hotel Bellevue a reception was given by the Medical Club of Philadelphia in honor of Dr. William M. Welch, president of the State Medical Society of Pennsylvania.

Hospital Bequests.—By the will of Raphael Teller, legacies of \$500 each are made to the Jewish Hospital Association, and the Jewish Foster Home and Orphan Asylum. The will of Eliza G. Landreth, Philadelphia, provides that on the death of certain persons named \$5000 shall revert to St. Luke's Hospital of New York for the endowment of a free bed; that \$3000 is to revert to the West Philadelphia Hospital for Women, and that \$5000 shall go to the Episcopal Hospital to endow a free bed.

Suicide Increasing.—The coroner's report shows that in 1901 there were 153 suicides in Philadelphia, a rate of 12 to 100,000 population. In 1890 the rate was 9.1 to 100,000. This increase in the number of suicides is general throughout the country. Good authority states that in 1890, in 50 of the largest cities of the United States, the average number of suicides was 12 per 100,000 of population, while in 1901 it was 16.

Cripples for Lorenz.—Hundreds of cripples of various sorts have applied for treatment by Dr. Lorenz, at the clinic which he is soon to hold in Jefferson Medical College Hospital. From the large list of applicants 20 cases of congenital dislocation of the hip have been selected, and careful study made, including skiagrams. From this score of cases Dr. Lorenz will make his own selection for operation. The Medical Club of Philadelphia will give a reception in his honor.

Typhoid Epidemic.—Typhoid fever may be said to have reached an epidemic condition, and is still on the increase. The official record for the week ended November 15 is: deaths, 10; new cases, 148; as against 8 deaths and 124 new cases for the previous week. There are probably 800 cases under treatment in the city. The health authorities have not determined the source of infection. Portions of the city supplied with filtered water seem affected equally with those not so supplied.

Site for City Institutions.—It is stated on good authority that the subcommittee of City Councils' committee on city property are negotiating for a tract of 267 acres of land in the Fortieth ward, to be used as a site for a hospital for the insane, an almshouse, and a hospital for contagious diseases. The plan, generally favored, is to remove the insane and almshouse department from their present location at Blockley and on the latter site to remodel and build an institution for purely hospital purposes. This will include the erection of several fine steel and glass isolated pavilions for consumptives. There are now in the insane department of the Philadelphia Hospital 1300 inmates, and 1800 more are scattered in institutions throughout the state. It is proposed to provide accommodation for all of these in the new institution.

GENERAL.

Cholera Again Among Soldiers.—Another small development of cholera in the Army in the Philippines is reported from the Fifth Infantry, who are on guard over Manila's water supply. Nineteen cases were reported November 13, of whom 7 had died.

Leprosy Statistics in the Philippines.—The cases of leprosy reported as existing in the various provinces of the Philippines number 3,063. The number of male lepers is nearly double

that of the females, 2,092 cases are adults and 171 children; of the total number of victims 1,097 are married. The vast majority of cases are among members of the Filipino races. In the city of Manila there was only one death from leprosy in May. The report of the chief surgeon at Manila, just received at the war department, says:

Leprosy is found generally throughout the islands, probably more in the Vizayas than elsewhere. At the request of the commissioner of public health medical officers of the Army searched for and reported many cases during the year. From their reports it appears that former estimates of the number of cases of this disease were placed at too high a figure, as nothing approaching 30,000 sufferers was found. Reports were, however, incomplete, as numerous places were not visited.

The proposed leper colony is much feared by the people, thus leading to concealment of cases, and without careful study, which was not practicable, early leprosy is overlooked. No cases have appeared in soldiers, as might be expected in view of the supposedly long period of incubation. The leper colony for natives has not yet been established.

Dissatisfaction of Naval Surgeons.—Surgeon-General Rixey, in his annual report of the condition of affairs in the Medical Corps of the Navy, refers thus to the complaints that the prospect of promotion is too meager, the work too hard and the pay too small:

Hospitals with twice as many patients as in 1897 have fewer surgeons, vessels at sea have had their quota of medical officers cut down one-third or one half, and important shore stations must depend on the partial training of a pharmacist.

The hope entertained by young medical officers just entering the service for future distinction has been so little realized, however, that the resignations in 1901 numbered nearly one-fourth of the entries into service in the same period. The reasons leading up to these resignations could be traced to dissatisfaction with the opportunities for purely professional work and advancement offered by a Service overworked and undermanned.

New Semi-Military Medical Corps.—A bill has been drawn up in the interests of the volunteer and contract surgeons now in service in the Philippines providing for a semi-military medical corps analogous to the British Indian Medical Service, in which the officers are given military titles and rank. The organization as proposed is to consist of one assistant surgeon-general with the rank of colonel, four deputy surgeons-general, with the rank of lieutenant-colonel, forty surgeons with the rank of major, and one hundred assistant-surgeons with the rank of captain and first lieutenant (mounted). The pay and allowances to be the same as those of corresponding ranks in the regular army. In the original organization the assistant surgeon-general, two of the deputy surgeons-general and two of the surgeons are to be appointed from the regular medical corps of the Army, the remainder to be from the volunteer and contract surgeons who have had not less than one year in tropical service. All are to be appointed after examination, due credit being given previous service. All original vacancies remaining twelve months after the bill becomes a law are to be filled similarly to those in the regular Army medical service. The provisions as regards promotion, leave of absence, retirement, court martial, etc., are provided for, the service, while similar in functions to that of the Army, is strictly distinct, and when detailed to act under the civil authorities it is independent of military jurisdiction and subject only to the orders of the civil authorities and those of the Secretary of War. It is claimed that this bill will be a relief to the medical corps of the Army, and do away with the present temporary, unsatisfactory and expensive employment of volunteer and contract surgeons, beside abolishing the injustice of the present system to deserving officers of these classes.

CANADA.

A New Hospital.—The Ross Memorial Hospital, the gift of James Ross of Montreal, was formally opened at Lindsay, Ont., November 20. The hospital is a handsome structure consisting of a main building, and two wings, and has been donated to the town by Mr. Ross in commemoration of his mother.

Children's Hospital for Montreal.—It is intended that in the near future a hospital shall be erected in Montreal for the reception of children of eastern Canada suffering from such diseases as tuberculosis or deformities of the limbs or spine. The hospital may be called "The Children's Memorial Hospital to Queen Victoria," and will be built on Mount Royal or in the country immediately adjacent to the city.

Montreal Maternity Hospital.—The fifty-eighth annual meeting of the Montreal Maternity Hospital was held last week with Dr. T. G. Roddick in the chair. Mrs. James Ross has donated \$1000 to the hospital. A new building has been decided on, to cost \$100,000. The treasurer's report showed a balance of over \$5000; 239 patients were treated during the past hospital year, and only three deaths occurred; \$65,000 has already been collected for the building fund of the new hos-

pital and \$25,000 has been expended for the purchase of the site.

No Sanitarium By-Law for Toronto.—The Board of Health of Toronto has put an end to the hopes of the Anti-Consumption League for the submission of a by-law to the ratepayers for a municipal grant of \$50,000, with which to inaugurate a fund for the establishment of a free sanitarium within twelve miles of the city. The meeting of the board was addressed by Dr. Sheard, the medical health officer, who said Toronto was in a very much better position with regard to the treatment of consumption than it was a year ago. No bedridden consumptive would now be refused admission to a hospital, and since June 9 the Gravenhurst Sanitarium has received from the city twenty-seven incipient cases, for which the city was paying forty cents a day each.

Ontario Medical Council Matriculation.—For some time the medical students have been complaining that the standard of the matriculation examination in the Ontario College of Physicians and Surgeons was altogether too high. Members of the Medical Faculty in Toronto University have taken up the matter with the government, with the result that the Minister of Education will take steps to secure a settlement of the difficulty. The trouble seems to have been caused by the indefinite wording of a clause in the regulations which read: "He has passed the examination conducted by the Education Department of Ontario of the course prescribed for honor matriculation in arts, chemistry and physics." It is stated that so seldom does any candidate take honors in all subjects prescribed for this course, that students of medicine would be so limited as to almost make the examination prohibitory.

FOREIGN.

Scandinavian Journal of Therapeutics.—The foundation of the *Nordisk Tidsskrift for Terapi* is announced from Copenhagen. Dr. Marius Lauritzen is the editor, with the collaboration of prominent internists of the Scandinavian countries. It is to be published monthly by the Gyldendalske Boghandels Forlag.

Memorial Tablet to Kussmaul.—Czerny is the son-in-law of the recently-deceased German clinician Kussmaul. He has had the house at Kanderndorf where Kussmaul used to live marked with a tablet stating: "Adolf Kussmaul, later professor at Erlangen, Heidelberg, Freiburg and Strassburg, practiced here, 1850-1853."

Renewal of Opium Prescription by Druggist.—The German courts have recently fined a druggist \$50, and his assistant \$14, on account of the fact that they dispensed a prescription calling for opium, and renewed it about two thousand times for the same purchaser. The courts held that they should have consulted with the physician, the author of the prescription, before dispensing it an unusual number of times.

Golgi's Silver Jubilee.—The twenty-fifth anniversary of his entrance on his professional career was celebrated October 28, by the friends of Professor Golgi at Pavia. An *édition de luxe* of his own works in three large volumes was presented to the illustrious anatomist in the presence of a large gathering of noted scientists and statesmen, including Kölliker, who came from Würzburg to congratulate his old friend. Golgi is now in his eighty-sixth year and in the best of health.

Esmarch's Eightieth Birthday.—All wishing to contribute to the testimonial in honor of Frederick von Esmarch, the renowned German surgeon, whose name is so immortally connected with the care of the wounded on the battlefield, are asked to send their communications to the bank at Kiel or Tönning. The latter is his birthplace, and his friends are planning a celebration there Jan. 9, 1903. Contributions should be addressed to the Reichsbankhauptstelle, Kiel, or to the Städtische Spar- und Leihkasse at Tönning. Von Esmarch married the aunt of Kaiser Wilhelm and he has been the recipient of honors of all kinds at home and abroad.

LONDON LETTER.

The Disuse of Splints in Colles' Fracture.

At the Polyclinic Mr. Jonathan Hutchinson insisted that the ordinary treatment of Colles' fracture by splints is injurious. He contended that the carpal fragment is very short and usually can not be influenced by attempts at extension, and that when there is not firm impaction the broad surfaces of the broken bones lock them together so that subsequent movement is impossible. He insisted that the attempt to press fragments of broken bone into place by pads or splints is bad practice, and certain to result in stiffening from adhesions. These conclusions were arrived at many years ago by Mr. Hutchinson,

and they have been confirmed by radiography. A study of the valuable series of radiographs of Colles' fracture exhibited by Mr. Robert Jones of Liverpool at the recent meeting of the British Medical Association, did not reveal a single case in which advantage could have resulted from the use of splints. In the majority the displacement of the carpal fragment was insignificant, and no advantage could accrue from attempts to rectify it. In some there was no displacement. In the minority the displacement was inconsiderable, and rectification impossible. Mr. Hutchinson showed a case treated without splints, in which the patient could use her arm after a month, and although there was some displacement there was no stiffening. A radiograph of another case was shown in which there was deep impaction which could not have been remedied by splints. Here the treatment was a plaster-of-paris splint for 5 weeks, massage for a month, and breaking down of adhesions under chloroform. At the end of three months the condition was unsatisfactory. Mr. Hutchinson advocates this treatment only for Colles' fracture—fracture through the expanded carpal end of the radius. In fractures higher up splints may be necessary. But unless the ulna is also broken a splint is not usually necessary, for no great amount of shortening or lateral displacement can occur. His advice is: when there is displacement which can be removed by extension and returns when extension is remitted use a splint, not otherwise.

The Plague-Pandemic.

The Local Government Board has published a thick volume of reports and papers on bubonic plague by Dr. R. Bruce Low. During the three years dealt with in Dr. Low's report, plague has become widespread, and has extended to every continent. Not until the wave has once more receded and opportunity has been thus afforded for weighing all the facts now being accumulated throughout the world can the epidemiologic, administrative, or other lessons to be learned from it be summarized. The records to which Dr. Low has had access, though they go to confirm belief that as regards plague man and the rat are reciprocally infective, do not afford sufficient data for determining the degree to which man is in danger through the rat. So far as plague ashore is concerned, it appears that in some localities man and the rat suffered from plague coincidentally; that in others man suffered before the rat; and that in others the rat suffered before man. When in a particular district the one (man or the rat) has suffered plague antecedently to the other, the interval between invasion of the first and of the second species has been often variable, extending sometimes over weeks and months. Plague may prevail largely among men without rats becoming conspicuously affected, and conversely, the disease may cause large mortality among rats of a locality while exempting man. As regards plague on shipboard similar facts were forthcoming. The disease does not, under conditions of sea transit, appear to be at all readily conveyed from the rat to man or from man to the rat.

Plague and Cholera in India.

Since the autumn of 1896 plague has been epidemic in India. Official reports fall far short of the actual mortality, but it is known that during the period from September, 1896, to the end of June, 1901, there were 659,864 attacks and 525,401 deaths in the population, which in 1891 was 287,317,048. Cholera is regarded with far less fear than plague, though the ravages of the former disease far exceed those of the latter. The total deaths recorded from cholera for the years 1896, 1897, 1898, 1899 and 1900, were 2,148,149, while those from plague were 403,671.

Herpes Zoster of the Third and Fourth Cervical Distribution with Facial Paralysis.

Dr. A. Stanley Barnes showed a case of this rare condition at the Clinical Society. The patient was a man aged 40 years. On Sept. 30, 1902, he was exposed to cold, and next day noticed a few "pimples" on the right side of his neck. By October 3 the herpetic rash was fully out, but he had no pain. He continued at work, but on the 8th he found that the right side of his face was paralyzed. On admission to hospital next day there was a profuse herpetic rash over the third and fourth cervical distribution on the right side and the skin was slightly analgesic. There was no pain. There was complete right facial palsy. The electrical reactions were normal. Taste was lost on the right side of the tongue, front and back, but was preserved on the left side. There was some dulling of the sense of hearing, especially of the higher musical notes on the right side. By the 22d the rash had dried up and the facial paralysis was improving, the frontalis and platysma particularly showing signs of returning voluntary movement.

Post-Graduate Teaching in London.

The Associated Schools of Medicine in London for post-graduate teaching are issuing joint cards admitting to the clinical instruction of the following metropolitan hospitals and schools of medicine: Charing Cross, Guy's, King's College, Middlesex, St. Bartholomew's, St. George's, St. Mary's, St. Thomas' University College, and Westminster. The following special hospitals are also included in the scheme: the Brompton Hospital for Diseases of the Chest; the Hospital for Sick Children, Great Ormond Street; the London School of Tropical Medicine; the National Hospital for the Paralyzed and Epileptic, and the Royal London Ophthalmic Hospital. The cards will be available for qualified medical men, British, colonial or foreign; they are nontransferable, must bear the signature of the holder, and must be shown when required to the authorities of the schools or hospitals visited. They will admit the holder to hospital practice, but not to classes preparatory to any examination. The cards will be issued on personal application and on evidence of qualification being furnished between the hours of 12:30 and 3 p. m. any week day except Saturday, at the office of the Metropolitan Schools of Medicine, West Wing Examination Hall, Victoria Embankment, W. C. A card for three months costs \$35, one for six months \$50, with a further fee of \$25 for each additional six months.

PARIS LETTER.

The Recent Change in the Treatment of Appendicitis.

Two years ago the majority of surgeons in France were inclined to operate immediately on most cases of appendicitis, and this tendency was due to Professor Dieulafoy, who declares that no one should die of appendicitis and that an immediate operation is the only safeguard for a patient. A certain number of surgeons still cling to this formula, but they are generally found among the younger men, who perhaps lack the moderation and judgment that are apt to come with advancing years. A cursory glance through the medical literature that has appeared during the last two months demonstrates how diverse the opinions of some well-known men are, and how convinced they are that their opinion is surely unassailable. Dr. Savariaud, a surgeon who has just obtained a position in the hospitals, is firmly convinced that all the arguments of the "opportunistic school" can be readily laid aside. Operating on a patient who is suffering from an attack of appendicitis could in no wise hasten or cause his death, the disturbance caused by the surgical intervention in the natural formation of a localized abscess is of slight account, the false membranes already in existence can be removed, provided sufficient drainage is insured, post-operative hernias are more the result of faulty technique than of incising the abdominal wall at such a time, and, in short, not one single argument can, according to Savariaud, justify procrastination. Such statements are now, however, made much less frequently, and contrast singularly with the moderate statements made last September at the surgical congress at Brussels. The latter meeting presented a certain international character, as numerous invitations had been sent to the most important surgeons of other countries. Dr. Broca, surgeon of the new Trousseau Hospital for Children, gave a synopsis of his statistics since 1892, which proved instructive. For three years he considered it expedient to operate on all cases, with very few exceptions, and the mortality was 33 per cent. Out of 79 cases of appendicitis 7 were left untouched, 8 operated on after the attack, and 64 "*à chaud*," as it is called in French, with 26 deaths. His death rate in 1896 was 13.33 per cent., and only 10.85 per cent. in 1897, 1898 and 1899. One great trouble, as Broca well remarks, is that patients are purged two or three times by the physician, and the result is bad, if not fatal. It can hardly be said that the improvement shown in 1896, 1897, 1898 and 1899 was due to improved technique, but rather to his habit of temporizing. His colleague at the Trousseau Hospital, Dr. Kirmisson, had tried the immediate operation, with the result that he had 50 per cent. of deaths. He then turned to his former practice. If the operation could be performed the very first day the patient falls ill, there would be little danger of a fatal result, but it is generally only the third or fourth day that the physician calls the surgeon, and this injudicious treatment may sometimes have brought about disastrous results. Then there is the danger of operating and finding no disease of the appendix. One of the most reliable surgeons in Paris told me recently the history of a case, which showed how disastrous this might be for the surgeon. A surgeon with a world-wide reputation was called in to see an American suffering presumably from appendicitis. She was operated on, and on the appendix being removed her husband asked to have it handed to him. He proceeded to

send it to London, to be examined as to its pathology, and the reply was that there was no appreciable lesion. Such mistakes are not so very uncommon, neuralgia of the ovary, for instance, being taken for appendicitis. According to Monprofit, who spoke at the congress of surgery, the operation for appendicitis has gone through the same phases as that for salpingitis, and surgeons are getting more reserved.

Bonnaire's Treatment of Galactophoritis.

Dr. Bonnaire, a well-known accoucheur of the Paris hospitals, has been advocating the use of ice in the treatment of galactophoritis, and considers it more advantageous than the treatment recommended by Budin, which consists in removing the milk and pus by expression. The technic is as follows: the breast is washed carefully with an antiseptic solution, and then covered with a dressing dipped in a solution of corrosive sublimate or nitrate of silver in case there are any fissures. Over this should be placed a strip of flannel and then a rubber bag filled with chopped-up ice. The whole is kept in place by means of a piece of oil-silk and a bandage. When the inflammation has gone down, some milk should be drawn off to see if there is still any pus.

Post-Graduate Course in France.

The system of having post-graduate courses during the summer months seems to be at last established in Paris. During the month of October there were 10 different courses on ophthalmology, stomach troubles, laryngology, urinary diseases, massage, dermatology, electrotherapy, practical surgery, gynecology, mental diseases and practical therapeutics. Each course cost only 20 francs, which is certainly not expensive.

The Gynecological Congress in Rome.

At the congress of gynecology, held in Rome last September, it was a noteworthy fact that there were more physicians of French than of any other nationality. The subjects most thoroughly discussed were the use of abortion as a therapeutic measure, and the treatment of puerperal infection by hysterectomy. Professor Treub of Amsterdam made some remarks about the prudence shown by most of the surgeons present, and said that even American surgeons, who had a reputation for being audacious, had refrained from recommending this operation over much. In his report on the subject he had spoken of Dr. Rochard's opinion that in all cases of severe infection the operation should be performed when the patient's life is in danger. Further on he had said that Dr. Rochard's remark that since the adnexa were removed even when there was no immediate danger, surely it might be claimed advisable to remove the uterus, when the patient's life hung in the balance. Dr. Rochard was not at the congress, but sent an open letter to Professor Treub, which was published in the *Presse Medicale*. He spoke of Professor Terrier's opinion, which is as follows: "In grave forms of puerperal infection, total hysterectomy seems to me to be thoroughly indicated." Dr. Rochard has operated on six cases for puerperal infection when called in by an accoucheur, and he remarks that he could not very well remain inactive under such conditions.

Pozzi's Report on Cancer of the Uterus.

The treatment of cancer of the uterus was the subject of a report by Dr. Pozzi at the Rome congress. He insisted on the importance there was in distinguishing the various forms, those seen in young women being apt to be much more serious and run a more rapid course. Even the temperament of the patient was of some importance. Cancer of the body of the uterus is found more frequently than was at first imagined, statistics such as those of Tesson (1902) showing that the proportion was from one in four to one in ten. His own experience, however, did not carry this out. He had seen 214 cases of cancer and only 6 of them were of the body of the uterus. This variety of cancer does not spread so rapidly, and is generally seen in women who are past 55 or 60. It does not recur so readily. Three patients of Lauwers remained cured. Boissier had the same result; Steinbach reports 23 cases, out of which 13 remained cured after three or four years, and Winter has obtained 30 observations with only 16 cures after five years. This is far from being the case with cancer of the cervix. Burkhardt's researches show that only 26 per cent. of the cases seen can be operated on with some chance of success. During the last eleven years at Broca Hospital, only 80 out of 210 cases were such as to render hysterectomy justifiable. When the uterus can no longer be moved easily surgeons in France abstain from operating, and Pozzi's formula is that the importance of the operation should be in inverse ratio to the size and connections of the tumor. The complete operation, such as it is, practiced by Wertheim, Mackenrodt, and

Schauta does not find favor with Pozzi, though it was carried out two or three weeks ago in his service by Jonnesco of Bucharest. The importance of removing the glands seems to have been exaggerated, as they are rarely a cause of serious complications or death, which is generally due to hemorrhage, chronic septicemia or uremia.

Correspondence.

Use of Alcohol—An Appeal to Physicians.

HARTFORD, CONN., Nov. 6, 1902.

To the Editor:—It is a fact not often recognized that the medical profession as a body have during the last half century made three distinct declarations concerning the nature and effects of alcohol on the body. These declarations grew out of a sense of alarm at the dangerous use of alcohol and the need of a protest by medical men acting independently. The first was made in 1839, and was signed by 78 leading physicians in London, Edinburgh and Glasgow. It was a public statement declaring the use of alcohol as a food and beverage to be injurious and pointing out its damage to the body. The second declaration appeared in 1847 and declared that alcohol was not needed in health and that total abstinence gave the strongest promise of longevity. This declaration was signed by 2,000 physicians in England, on the continent and in this country. The third declaration appeared in 1871, and while reaffirming the statements of the former manifestos declared alcohol to be a poison and a most powerful drug, and one that should not be used except by physicians and with care and caution. This was signed by over 4,000 physicians, including some of the leading men in every part of the world. The names of thirty American physicians appeared on this role. A fourth manifesto or declaration of opinions has been projected and is now being circulated for signatures among leading physicians in every civilized country. The following is the text of this declaration:

The purpose of this manifesto is to have a general agreement of opinions of all prominent physicians in civilized countries concerning the dangers from alcohol, and in this way give support to the efforts made to check and prevent the evils from this source.

In view of the terrible evils which have resulted from the consumption of alcohol, evils which in many parts of the world are rapidly increasing, we, members of the medical profession, feel it to be our duty, as being in some sense the guardians of the public health, to speak plainly of the nature of alcohol, and of the injury to the individual and the danger to the community which arise from the prevalent use of intoxicating liquors as beverages.

We think it ought to be known by all that:

1. Experiments have demonstrated that even a small quantity of alcoholic liquor, either immediately or after a short time, prevents perfect mental action, and interferes with the functions of the cells and tissues of the body, impairing self-control by producing progressive paralysis of the judgment and of the will; and having other markedly injurious effects. Hence alcohol must be regarded as a poison, and ought not to be classed among foods.

2. Observation establishes the fact that a moderate use of alcoholic liquors, continued over a number of years, produces a gradual deterioration of the tissues of the body, and hastens the changes which old age brings, thus increasing the average liability to disease (especially to infectious disease), and shortening the duration of life.

3. Total abstinence, other conditions being similar, can perform more work, possess greater powers of endurance, have on the average less sickness, and recover more quickly than non-abstinence, especially from infectious diseases, while they altogether escape diseases specially caused by alcohol.

4. All the bodily functions of a man, as of every other animal, are best performed in the absence of alcohol, and any supposed experience to the contrary is founded on delusion, a result of the action of alcohol on the nerve centers.

5. Further, alcohol tends to produce in the offspring of drinkers an unstable nervous system, lowering them mentally, morally and physically. Thus deterioration of the race threatens us, and this is likely to be greatly accelerated by the alarming increase of drinking among women, who have hitherto been little addicted to this vice. Since the mothers of the coming generation are thus involved the importance and danger of this increase can not be exaggerated.

Seeing, then, that the common use of alcoholic beverages is always and everywhere followed, sooner or later, by moral, physical and social results of a most serious and threatening character, and that it is the cause, direct or indirect, of a very large proportion of the poverty, suffering, vice, crime, lunacy, disease and death, not only in the case of those who take such beverages, but in the case of those who are unavoidably associated with them, we feel warranted, nay, compelled to urge the general adoption of total abstinence from all intoxicating liquors as beverages as the surest, simplest, and quickest method of removing the evils which necessarily result from their use. Such a course is not only universally safe, but it is also natural.

We believe that such an era of health, happiness, and prosperity would be inaugurated thereby that many of the social problems of the present age would be solved.

This has already received the signatures of over 1,000 physicians, principally in England, Germany and France. Its

importance and practical value as a statement of the experience and judgment of the leading physicians of the world outside of all associations and as scientific men can not be overrated. This declaration with its signatures is to be published and circulated in the early part of the coming year and will have a historic interest as indicating medical sentiment at the beginning of the century and giving assistance to the efforts made to correct public sentiment and assist in the prevention of the evils which follow from the indiscriminate use of alcohol. I have been asked to solicit signatures to this manifesto from leading American physicians. The matter is a purely scientific one, and the signature of each physician stands not only for himself personally, but as a representative thinker and student in a cause, the solution of which would be of great interest in the future. I should be very glad to receive the names, titles and addresses of any physician who is willing to aid in making this a distinctive movement for the benefit of the world. American physicians should be equally enthusiastic and prompt to lend their signatures as those in the wine-drinking countries of Europe. A postal card, giving the address and titles, is earnestly solicited from every physician who would like to be represented in this last great movement to correct and help overcome one of the great evils of the age.

T. D. CROTHERS, M.D.

Methods for Prevention of Tubercular Infection at Mount St. Rose Sanatorium.

ST. LOUIS, Nov. 8, 1902.

To the Editor:—In the new sanatorium for tuberculosis in St. Louis, the greatest care is taken to prevent infection and the spread of the disease. As some of the methods employed are not in general use, I may be pardoned for mentioning them.

Recognizing that the greatest danger of transmission is conveyance by eating utensils, clothing and the sputum, these vehicles receive special attention. All dishes when carried from the patients' table are at once placed in boiling water in a large, closed vessel kept for this purpose only, and boiled. When patients are admitted, all outer clothing is put into a tight clothespress and thoroughly fumigated, as is also done at intervals. In case of death, all such apparel is fumigated before it is given to the relatives. All underclothing, sheets, towels, etc., before being taken to the laundry, are placed in a steam-box where, under pressure of not less than 100 lbs., they are exposed to superheated steam for 20 minutes and then boiled in one division of the laundry-room. As bacilli are destroyed at less than 170, this seems sufficient.

The care of the sputum is as thorough as possible. To prevent the carrying of bacilli by flies all the cups and cuspidors are kept covered and emptied frequently. No possible excuse is made for any patient expectorating on the floors, verandas or grounds. In place of the ordinarily used germicides, the concentrated lye of the shops (crude hydrate of potash) is used. It has the advantage of being cheap, odorless and thoroughly dissolving the masses of sputum, saponifying necrotic tissue and destroying every particle of germ life. The cuspidors are specially made for the hospital. They are of iron and in two pieces. The lid is easily removed, being held in place by a plain socket and lifted by a pedal. It falls in place by gravity. The box of the cuspidor is plain and square, but with rounded corners. It rests on four small projections or feet, which are perforated in the horizontal line. When the cuspidor is to be cleaned, it is placed in a carrying box and taken to the engine room where the contents, including the papers from the individual sanitary cups, are mixed with sawdust. A forked iron rod is run through the perforated feet and the box is thrust into the furnace. The rod is withdrawn and the furnace door closed. After awhile the box is turned over in the fire and the contents emptied. Both trouble and danger are reduced to a minimum. The appearance of the cuspidor is not objectionable, for the lid which slightly overhangs the box is arched to relieve its plainness and is frequently brushed with a thin solution of aluminum paint.

With this care, seemingly perfect ventilation, plumbing and germ-proof walls and floors, it is believed that any danger from infection can be prevented more thoroughly than in the home or average resort.

WILLIAM PORTER, M.D.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

IS ELECTRICITY GERMICIDAL?

LINTON, IND., Oct. 24, 1902.

To the Editor:—Can you give me reliable information in regard to the following: 1. Is electricity in any form and in any strength a germicide to all bacteria, when the temperature is kept low? 2. If so, what form and what strength? Is the α -ray germicidal?

M. N. THAYER, M.D.

ANS.—1. The experiments of Zeit (THE JOURNAL A. M. A., Nov. 30, 1901) show that electricity *per se* has practically no germicidal action. The destruction of bacteria caused by the passage of an electric current through cultures is explained by the generation of heat or the liberation of germicidal chemicals or other physical or chemical facts. 2. The germicidal properties of α -rays proper are practically nil. The effect produced by α -rays on bacteria in tissues, however, is well established, the result being explainable on increased phagocytosis of the cells caused by α -rays or some other change produced by α -rays in the tissues whereby they are rendered better able to cope with organisms.

State Boards of Registration.

Western Medical Reciprocity.—The presidents and secretaries of the state boards of health and licensing boards of Illinois, Nebraska, Kansas, Missouri and New Mexico, met at Kansas City, November 17, pursuant to a call which was noticed in THE JOURNAL of October 25. The representatives were: Illinois, Dr. George W. Webster, Chicago, president of the board; Nebraska, Drs. George H. Brash, Beatrice, secretary, and Benjamin F. Bailey, Lincoln, president; Kansas, Drs. Henry W. Robey, Topeka, secretary, and Edwin D. Packer, Osage City, vice-president; Missouri, Drs. A. W. McAlester, Columbia, president, and Winn F. Morrow, Kansas City, secretary; New Mexico, Dr. Walter G. Hope, Albuquerque, secretary. After considerable preliminary debate the following preamble and resolutions were unanimously adopted:

WHEREAS, The majority of the physicians in the United States are in favor of an improved and a higher standard of medical education, and

WHEREAS, They are also desirous of doing justice to all, of recognizing the value of experience as a qualification, and of doing justice to the veterans in the profession, and

WHEREAS, Any scheme of reciprocity to meet with favor and be enduring, must be in accord with these sentiments,

Therefore, Be It Resolved, First—That for those graduating in medicine hereafter, reciprocity in license should be based on the following:

- Uniformity in preliminary entrance requirements.
- Uniformity in the length and character of the medical course.
- Uniformity in the character of the examination.
- Uniformity in legislative enactments which shall permit, or authorize reciprocity.

Be It Also Further Resolved, That it is the sense of this meeting that the "Preliminary entrance requirement" should be satisfactory documentary evidence under oath of a high school education, of not less than three years' duration.

Be It Also Further Resolved, That it is the sense of this meeting that the medical course should consist of not less than four terms, or courses, of at least seven months each, in four separate calendar years, and that each term should consist of not less than eight hundred hours of actual work.

Be It Also Further Resolved, That it is the sense of this meeting that by "uniformity in character of the examination," we mean that with the exception following, all applicants should be examined in at least the following branches:

- Anatomy; 2. Bacteriology; 3. Chemistry; 4. Materia Medica and Therapeutics; 5. Obstetrics and Gynecology; 6. Pathology; 7. Physiology; 8. Practice of Medicine; 9. Surgery.

Be It Also Further Resolved, That the foregoing should be considered the minimum qualifications for admission to examination for license, and

Be It Further Resolved, That it is the sense of this meeting that each examining and licensing board or state board of health should be empowered by legislative enactment, to accept in lieu of an examination, all of the following:

- A diploma from a recognized medical school.
- A license from a reciprocating state board of health or licensing board.
- A certificate from the state board of health or licensing board, where the applicant last resided, showing at least ten years of reputable practice since graduation from a recognized medical school.

Rhode Island Examination.—Dr. Gardner T. Swarts, secretary of the Rhode Island State Board of Health, reports the examination held at Providence, R. I., July 3, 1902, as follows: Number of subjects examined in, 7; questions, 70; percentage,

75; written examination; number examined, 19; passed, 16; failed, 3.

Candi- date.	Sch. of date. Pract.	PASSED.		
		College.	Year Grad.	Per Cent.
167	R.	Howard University	1902	84.9
169	R.	Howard University	1902	90.1

New Hampshire Announcements.—The next examination is at Concord, Dec. 9 and 10. No licenses issued by state.

or diplomas from medical colleges, are endorsed by the regent in place of examination, with one exception, graduates from Dartmouth Medical School may receive a certificate on presentation of diploma, if said diploma shall have been issued between the enactment of the Medical Law, March, 1897, and Jan. 1, 1903. Further information may be had from Channing Folsom, regent.

Medical Organization.

Organization Work in Kentucky.

BOWLING GREEN, KY., Nov. 17, 1902.

To the Editor:—At its annual meeting in 1901 the Kentucky State Medical Society arranged to keep in touch with the plan of reorganization then being formulated by the American Medical Association, by appointing a committee to revise its constitution and by-laws. This committee consisted of Drs. Steele Bailey, the secretary; Henry E. Tuley and J. N. McCormack, and at the annual meeting, held at Paducah in 1902, this committee reported, and, after full discussion, extending at intervals throughout the session, the society unanimously adopted the constitution and by-laws proposed by the association, without change, except the ratio of delegate representation from county societies was made one for each fifty, instead of one for each one hundred members, and such verbal alterations as related to the time and place of meeting.

Much enthusiasm was manifested on every hand during the session, and steps were at once taken to push the work of organization systematically in the various counties. The state was divided into eleven councilor districts, corresponding to the congressional districts, except that the fifth district—the city of Louisville—and the sixth district, lying contiguous to it on the Ohio river, were combined into one councilor district, and the eleventh congressional district, a large mountain region covering nineteen counties, was divided into two councilor districts. Provision was made for paying the traveling expenses of the councilors, and every member of the state society pledged himself to give them support.

Following, by councilor districts, is given the name and address of each councilor, the county societies organized and chartered, with the names and addresses of the officers of each society. All of the societies except six were organized under the new plan, giving thirty-nine county societies formed since the meeting of the state society.

FIRST DISTRICT.—Dr. J. R. Coleman, Paducah, councilor.

Ballard County Society: President, Dr. N. L. Rogers, Wickliffe; secretary, Dr. Z. W. Morgan, Wickliffe.
Calaway County Society: President, Dr. G. H. Covington, Wadesboro; secretary, Dr. W. H. Graves, Murray.
Fulton County Society: President, Dr. P. B. Curlin, Hickman; secretary, Dr. Samuel Cohn, Fulton.
Hickman County Society: President, Dr. W. R. Moss, Clinton; secretary, Dr. W. A. Craig, Clinton.
Lyon County Society: President, Dr. J. H. Hussey, Eddyville; secretary, Dr. D. J. Travis, Eddyville.
McCracken County Society: President, Dr. S. Z. Holland, Grahamville; secretary, Dr. T. U. Moss, Woodville.

SECOND DISTRICT.—Dr. James D. Sory, Madisonville, councilor.

Christian County Society: President, Dr. W. W. Ray, Hopkinsville; secretary, Dr. R. L. Woodard, Hopkinsville.
Daviss County Society: President, Dr. S. J. Harris, Philpot; secretary, Dr. J. J. Rodman, Owensboro.
Hancock County Society: President, Dr. Albert Griffin, Utility; secretary, Dr. C. R. Lightfoot, Hawesville.
Henderson County Society: President, Dr. W. J. Stone, Henderson; secretary, Dr. W. S. Porwood, Henderson.
Hopkins County Society: President, Dr. B. T. Earle, Charleston; secretary, Dr. R. W. Long, Madisonville.
Union County Society: President, Dr. R. L. Martin, Bordley; secretary, Dr. I. D. Winston, Sturgis.
Webster County Society: President, Dr. C. L. Edwards, Sebree; secretary, Dr. J. A. Goodson, Dixon.

THIRD DISTRICT.—Dr. A. T. McCormack, Bowling Green, councilor.

Allen County Society: President, Dr. W. B. Ray, Scottville; secretary, Dr. J. B. House, Scottville.
Muhlenburg County Society: President, Dr. J. T. Woodburn, Bremen; secretary, Dr. Augustus Lewis, Greenville.
Todd County Society: President, Dr. W. B. Jefferson, Elkton; secretary, Dr. T. E. Bruce, Elkton.
Warren County Society: President, Dr. H. P. Cartwright, Bowling Green; secretary, Dr. John H. Blackburn, Bowling Green.

FOURTH DISTRICT.—Dr. R. C. McChord, Lebanon, councilor.
Larue County Society: President, Dr. W. E. Rodman, Hodgenville; secretary, Dr. E. S. Smith, Hodgenville.

Marion County Society: President, Dr. Edward Kelley, Lebanon; secretary, Dr. R. C. McChord, Lebanon.
Meade County Society: President, Dr. D. C. Pusey, Brandenburg; secretary, Dr. W. T. Miles, Brandenburg.
Ohio County Society: President, Dr. J. W. Taylor, Cromwell; secretary, Dr. S. J. Wedding, Hartford.

FIFTH AND SIXTH DISTRICTS.—Dr. Louis Frank, Louisville, councilor.

Jefferson County Society: President, Dr. William Bailey, Louisville; secretary, Dr. R. A. Bate, Louisville.

SEVENTH DISTRICT.—Dr. David Barrow, Lexington, councilor.
Fayette County Society: President, Dr. J. C. Carrick, Lexington; secretary, Dr. G. P. Sprague, Lexington.

Henry County Society: President, Dr. W. T. Coblin, Campbellsburg; secretary, Dr. A. P. Dowden, Eminence.
Owen County Society: President, Dr. S. A. Veal, Squiresville; secretary, Dr. J. P. Lindsey, Owenton.

Scott County Society: President, Dr. Caswell Graves, Paynes Depot; secretary, Dr. J. C. Lewis, Georgetown.

Woodford County Society: President, Dr. J. C. Lowery, Troy; secretary, Dr. W. C. McCauley, Versailles.

EIGHTH DISTRICT.—Dr. Steele Bailey, Stanford, councilor.

Anderson County Society: President, Dr. O. L. Townsend, Orr; secretary, Dr. L. C. Moffitt, Alton Station.

Boyle County Society: President, Dr. W. A. Brown, Parkesville; secretary, Dr. J. C. Bogle, Danville.

Garrard County Society: President, Dr. H. C. Herring, Lancaster; secretary, Dr. H. M. Grant, Lancaster.

Jessamine County Society: President, Dr. Charles Mann, Nicholasville; secretary, Dr. J. A. Vanarsdall, Nicholasville.

Lincoln County Society: President, Dr. Hawkins Brown, Hustonville; secretary, Dr. L. B. Cook, Stanford.

Shelby County Society: President, Dr. Curtis Austen, Bagdad; secretary, Dr. T. E. Bland, Shelbyville.

NINTH DISTRICT.—Dr. J. E. Wells, Cynthiana, councilor.

Carter County Society: President, Dr. J. D. Muters, Rush; secretary, Dr. N. K. Williams, Willard.

Harrison County Society: President, Dr. Josephus Martin, Cynthiana; secretary, Dr. Marshall McDowell, Cynthiana.

Mason County Society: Dr. James Shackelford, Maysville; secretary, Dr. A. G. Browning, Maysville.

Robertson County Society: President, Dr. J. B. Wood, Mt. Olivet; secretary, Dr. W. S. Chandler, Mt. Olivet.

TENTH DISTRICT.—Dr. I. A. Shirley, Winchester, councilor.

Breathitt County Society: President, Dr. C. H. Williams, Jackson; secretary, Dr. J. P. Boggs, Jackson.

Clark County Society: President, Dr. N. V. Frewitt, Winchester; secretary, Dr. I. A. Shirley, Winchester.

Lee County Society: President, Dr. M. F. Reed, Beattyville; secretary, Dr. J. H. Evans, Beattyville.

Montgomery County Society: President, Dr. W. S. Van Antwerp, Mt. Sterling; secretary, Dr. C. B. Duerson, Mt. Sterling.

Morgan County Society: President, Dr. W. G. Carter, West Liberty; secretary, Dr. E. C. Gevidon, Grassy Creek.

Powell County Society: President, Dr. A. M. Swango, Stanton; secretary, Dr. C. D. Mansfield, Stanton.

Wolfe County Society: President, Dr. B. D. Cox, Fincastle; secretary, Dr. J. H. Stamper, Campton.

ELEVENTH DISTRICT.—Drs. G. M. Reddish, Somerset, and L. L. Robertson, Middlesboro, councilors.

Casey County Society: President, Dr. W. T. Garner, Humphrey; secretary, Dr. D. S. Floyd, Joyce.

Pulaski County Society: President, Dr. G. M. Reddish, Somerset; secretary, Dr. A. W. Cain, Somerset.

The work is under way in many other counties and it is the hope of its friends to reach and organize the profession in a large majority of these before the next meeting of the state society. That the profession is ripe for organization everywhere is shown by the ease in forming societies in every county visited by any one at all acquainted with the work. So far several of the councilors have done practically nothing, the county organizations in their districts having resulted from other influences, but it is hoped that each of these gentlemen will meet his responsibilities in the near future. Especial mention should be made of the faithful and highly successful work already done by Dr. I. A. Shirley, councilor in the tenth district, who, in a region largely mountainous and sparsely settled, has organized seven promising county societies. He expects to reach several other counties within the next few weeks, and has then promised to do some missionary work in counties outside of his district.

The president of the state society, Dr. W. W. Richmond, and the secretary, Dr. Steele Bailey, are earnestly supporting every effort being made for the organization and elevation of the profession, and Kentucky promises to be in the line with her sister states by the next meeting of the Association.

Respectfully,

J. M. MCCORMACK.

Weakley County (Tenn.) Medical Society.

The society was organized at Dresden, Tenn., November 3. The following officers were elected: Dr. Vincent A. Biggs, Martin, president; Dr. Adolphus Finch, Dresden, and Dr. Mitchell, Greenfield, vice-presidents, and Dr. Carl Finch, Dresden, secretary and treasurer.

Henderson County (Tenn.) Medical Society.

This society was organized at Lexington October 28 with 19 members. The following officers were elected: Dr. Martin P. Boyd, Farmville, president; Drs. John M. Arnold, Middeford, and John H. Howard, Lexington, vice-presidents; Dr. C. H. Johnston, Lexington, secretary, and Dr. William Watson, Lexington, treasurer.

Emmet County (Mich.) Medical Society.

The physicians of Emmet County met at Petoskey October 23 and organized a county society to be a branch of the state society with the following officers: Dr. Henry T. Calkins, president; Dr. John J. Reyecraft, vice-president; Dr. George W. Nihart, treasurer, and Dr. George E. Reyecraft, secretary, all of Petoskey.

Ottawa County (Mich.) Medical Society.

A new county medical society was organized at Grand Haven October 28, whose membership includes the regular physicians of Ottawa County. The Grand River Valley Medical Society has been merged into the new organization, which is a branch of the Michigan State Medical Society. The following officers were elected: Dr. Henry Kremers, Holland, president; Drs. Cyril P. Brown, Spring Lake, and Byron B. Godfrey, Holland, vice-presidents; Dr. Daniel G. Cook, Holland, secretary, and Dr. Abraham Leenhouts, Holland, treasurer.

Marriages.

C. LE VAN MANDERBACH, M.D., St. Louis, to Miss Nellie Howell of Kansas City, Mo.

WILLIAM DONOVAN, M.D., U. S. A., to Miss Julia Dunne, both of New York City, November 5.

FREDERICK BENTLEY, M.D., Danforth, Ill., to Miss Hattie Barton of Chicago, November 3.

ISAAC L. WATKINS, M.D., to Miss Nellie Thigpen, both of Montgomery, Ala., November 5.

GEORGE W. PAYNE, M.D., Bardwell, Ky., to Miss Alda Moore of Arlington, Tenn., November 11.

AILEEN M. BETTEYS, M.D., Oxford, Mich., to Robert M. Corbit of Clarence, Iowa, October 22.

JOHN C. HATHAWAY, M.D., to Miss Fern Kimball, both of Mechanicsburg, Ohio, November 4.

WILLIAM F. HUGHEY, M.D., Yellowbud, Ohio, to Miss Maud Shotts of Denver, Ohio, October 29.

ALEXANDER E. LOW, M.D., Chicago, to Miss Adelaide M. Butts of Janesville, Wis., October 22.

ERNEST H. RAWLS, M.D., Soperton, Ga., to Mrs. Lottie Browne of Savannah, Ga., October 30.

IRWIN W. BLAKE, M.D., Ladysmith, Wis., to Miss Irene Dennis of Viroqua, Wis., November 1.

ARTHUR L. KELSEY, M.D., to Miss Eunice Weston Blanchard, both of Santa Paula, Cal., October 31.

JAMES E. CHIPPS, M.D., Birdsville, Ky., to Miss Helen D. Brashear of Louisville, Ky., October 29.

J. GILBERT SMITH, M.D., McDonough, Ga., to Miss Eunice Landrum of Atlanta, Ga., November 12.

RICHARD M. LITTLE, M.D., Dresden, Tenn., to Miss Ina Allen Bobbitt of Gleason, Tenn., November 12.

AART VAN WESTRIENEN, M.D., Kenosha, Wis., to Miss Kate Pals of Grand Haven, Mich., October 29.

C. HOWARD LEWIS, M.D., to Mrs. Georgeanna Kelly, both of Baltimore, at Philadelphia, November 8.

SAMUEL S. LATHROP, M.D., Norwich, Conn., to Miss Janet Torrance of Greeneville, Conn., November 5.

THEODORE D. PALLMAN, M.D., New Haven, Conn., to Miss Ruth Hall of New York City, November 12.

WALTER S. PATTERSON, M.D., Allegheny, Pa., to Ella H. Hackett, M.D., of Philadelphia, November 3.

HARRY CLINTON TULL, M.D., Jesterville, Md., to Miss Edna Williams Gillis of Salisbury, Md., October 29.

WALTER HERBERT BROWN, M.D., Youngwood, Pa., to Miss Irene Gibbons of Washington, D. C., October 29.

JAMES THOMAS RUSHIN, M.D., Tallassee, Ala., to Miss Bessie May Elsberry of Montgomery, Ala., November 4.

MANUEL V. SYLVIA, M.D., New Bedford, Mass., to Miss Georgiana Goodwin of Natick, R. I., October 30.

FRANK A. MILLARD, M.D., Detroit, to Miss Margaret Josephine Wilkinson of Windsor, Ontario, October 30.

C. M. SOUTHARD, M.D., Zanesville, Ohio, to Miss Georgia Gault of Columbus, Ohio, at Newark, Ohio, October 29.

WILLIAM H. DE LA FAYETTE, M.D., Nickerson, Kan., to Miss Mabel Evans of Kansas City, Mo., at Nickerson, Mo., October 27.

CHARLES M. EDWARDS, M.D., Richmond, Va., son of Dr. Landon B. Edwards, to Miss Lelya Le Moyne Gahagan of New York City, October 29.

Deaths.

Thomas F. McManus, M.D. Western Pennsylvania Medical College, Pittsburg, 1890, an active member of the Allegheny County Medical Society, died at his home in Pittsburg, November 5, after an illness of one week, from pneumonia complicating typhoid fever, aged 42.

Andrew G. Clark, M.D. Transylvania University, Lexington, Ky., a practitioner for nearly 70 years in Parkersburg, W. Va., died at his home in that city, November 7, aged 93. The bulk of his estate is left for the building of a hospital in Parkersburg.

Henry M. Cox, M.D. University of Michigan, Ann Arbor, 1868, for many years president of the Board of Health of Washington, N. J., died at his home in that place, November 5, from cancer of the stomach, after a long illness, aged 59.

Carl Pesold, M.D. St. Louis College of Physicians and Surgeons, 1892, major and surgeon, First Infantry, Missouri National Guard, died at his home in St. Louis, November 6, from liver disease, after an illness of one year, aged 44.

Wilmot Ayres, M.D. Baltimore Medical College, 1883, surgeon at Camp Meade during the Spanish-America War, died at his home in Harrisburg, Pa., from pneumonia, after an illness of five weeks, November 7, aged 54.

J. Newton Walker, M.D. University of Pennsylvania, Philadelphia, 1856, for many years a resident of Cape May Point, committed suicide by shooting, August 15. His body was not found until November 10.

Richard N. Hawkins, M.D. Miami Medical College, Cincinnati, 1868, of Birmingham, Ala., died at his residence in Elyton, November 6, from Bright's disease, after an illness of several weeks, aged 56.

John A. Watson, M.D. University of Maryland, Baltimore, 1872, died at his home in Asheville, N. C., November 4, from acute uremia, after an illness of only a few hours, aged 53.

L. C. Beal, M.D. Western Reserve University, Cleveland, Ohio, 1884, died at his home in Uniontown, Pa., October 29, from paralysis after an illness of three days, aged 52.

John E. Mealy, M.D. College of Physicians and Surgeons, Columbus, Ohio, 1896, Girard, Ohio, died suddenly at Cleveland, Ohio, November 2, from heart disease, aged 30.

John W. James, M.D. Jefferson Medical College, Philadelphia, 1895, died at his home in Pittsburg, Pa., November 6, from apoplexy, after a lingering illness, aged 65.

William Thomas Lavvorn, M.D. Atlanta (Ga.) College of Physicians and Surgeons, 1901, died from consumption at his home in Newell, Ala., November 1, aged 28.

A. Melville Tully, M.D. late captain and assistant surgeon, U. S. Army, died at Las Vegas, N. M., November 5, from tuberculosis, after a long illness, aged 48.

John C. Lightfoot, M.D. University of Tennessee, Nashville, 1891, died at his home near Drake, Ky., October 31, from consumption, after a long illness, aged 35.

Harry H. Young, M.D. Columbus (Ohio) Medical College, 1890, died from hemorrhage of the stomach in the Hartman Hospital, Columbus, October 18, aged 34.

Archibald B. Terry, M.D. Tulane University, New Orleans, La., 1898, was instantly killed by a fall from his buggy, near his home in Longview, Texas, October 30.

Roy H. McCarl, M.D. Omaha (Neb.) Medical College, 1896, Wellman, Iowa, died at Omaha, November 2, after an operation for appendicitis, aged 29.

Walter E. Griffin, M.D. University of Michigan, Ann Arbor, 1896, assistant surgeon, U. S. Navy, died at Cavite, Philippine Islands, October 28.

A. M. Powell, M.D. Washington University, St. Louis, 1860, died at his home in Collinsville, Ill., November 3, after a brief illness, aged 67.

John V. Everett, M.D. Tulane University, New Orleans, 1876, died at his home in Weatherford, Texas, October 28, from Bright's disease.

George A. Osborne, M.D. Medical College of Indiana, Indianapolis, 1873, died at his home in South Bend, Ind., November 5, aged 80.

Amos Thornburg, M.D. Atlanta (Ga.) Medical College, 1859, of Chattanooga, Tenn., died recently at Birmingham, Ala.

John C. Reese, M.D. Medical College of Georgia, Augusta, 1857, died suddenly at his home in Reesburg, Ga., November 30.

Henry C. Summers, M.D. University of Cincinnati, 1878, died suddenly at his home in Daleville, Ind., November 4.

Fred D. Miller, M.D. College of Physicians and Surgeons, Baltimore, 1882, recently died at his home in Alden, Mich.

Edward Little, M.D. University of Buffalo (N. Y.), 1862, died at his home in Buffalo, October 30, aged 75.

Deaths Abroad.

Lennox Browne, F.R.C.S. (Edin.), a well-known specialist in diseases of the throat, died from carcinoma of the liver at Northwood, England, November 2, aged 61. Mr. Lennox Browne was admitted to membership in the Royal College of Surgeons in England in 1863, and in 1873 was made a Fellow of the Edinburgh College. He practiced for a time in Australia, but returned in 1867 to London, where he became assistant to the late Sir Morell MacKenzie, with whom he was associated for seven years, and during that time was a member of the staff of the Hospital for Diseases of the Throat, Golden Square. In 1874 he was one of the founders of the Central London Throat, Nose and Ear Hospital and was senior surgeon to that hospital for many years. On retirement from active practice he was appointed consulting surgeon. He was also surgeon and oral surgeon to the Royal Society of Musicians, Royal Choral Society and Dramatic Sick Fund. He was original fellow and sometime president of the British Laryngological and Rhinological Association and fellow of the Medical and Pathological societies, honorary member of the Philadelphia Medical Society, and corresponding fellow of the American Laryngological Association. He was a large contributor to the literature of his specialty, his chief work being a text-book entitled "The Throat and Nose, and Their Diseases," the fifth edition of which appeared in 1898.

Dr. J. Hermann of Vienna, noted as an antagonist of mercurial treatment of syphilis.—Dr. Moritz Fraenkel of Dessau, well known as an alienist and in charge of the insane asylums of Anhalt.—Dr. Ledoux-Lebard, laboratory chef at the Paris Pasteur Institute, in his fifty-fourth year, author of numerous studies on the pseudo-tubercle bacilli, etc.—Dr. E. Hahn, a prominent surgeon at Berlin, director of the surgical service at the Friedrichshain Hospital, November 1, 61 years of age.

Dr. R. A. Monteiro, dean and professor of clinical medicine at Bahia, Brazil. He was born in 1839, married at 17, and died September 15, victim of an internal cancer. One of his latest works was on "Certain Difficulties in the Diagnosis of Beri-Beri and of Nephritis."

Miscellany.

Serum-Therapy in Scarlatina.—In his report of his experiments with the serum treatment of scarlatina, in the *Montreal Med. Jour.* for October, Charlton first gives due credit to Moser for independent work in the same line and priority in publication. His own work dates back two years and the striking agreement of the results with those of the Austrian physician is noticed. Like other observers, he found the streptococci abundant in the blood, urine, pus, etc., of scarlatina, but he is not convinced that it is the germ of the disease. On the contrary, he looks on it as the producer of a secondary affection to which most if not all the unfavorable complications of the disorder are due, hence the call for an anti-streptococcus serum to counteract the toxins and destroy their producers. After experimenting with a number of different sera without success, he finally obtained one prepared by Dr. Hubbert of Detroit. Thus far he has used it in 15 cases, all severe, with 13 recoveries almost without complications. There were two deaths,

but one of these was moribund when seen and died in four hours, the other was suffering from a severe pneumonia on admission to the hospital, and though improving somewhat, succumbed five days later in an attack of laryngeal diphtheria. The quantity of serum used was moderate, usually 20 c.cm., but if a large quantity was required this dose was repeated. In this respect it seems more active than that of Moser. The effect was usually prompt. The temperature began to fall in two hours and became normal in from two to four days. No other treatment except stimulation the first three or four days and the usual attention to laxatives, diet and rest. No bad symptoms appeared from the use of the serum. He does not credit it with curing scarlatina, but its timely use allays unfavorable symptoms, overcomes complications, and tends to recovery. The results of the injections are thus summed up: 1. Rapid subsidence of fever. 2. Accompanying decrease and improvement of pulse. 3. Prevention on marked improvement of such complications as cervical adenitis. 4. Rapid and favorable convalescence in the majority of cases. Dr. Charlton hesitates to lay most stress on the reduction of the mortality, though he should have expected, from his experience, a fatal result in most of these cases. But he has never before seen the disease pass so suddenly from a severe—not to say alarming—to a relatively mild condition. He asks for co-operation in this study of the serum treatment of scarlatina.

Societies.

COMING MEETINGS.

Indian Territory Medical Association, Muskogee, Dec. 2-3, 1902.
Western Surgical and Gynecological Association, St. Joseph, Mo., Dec. 29, 1902.

Vermilion County (Ill.) Medical Society.—At the annual meeting of this society, November 9, Dr. Henry F. Becker, Danville, was elected president; Dr. Frazier N. Cloyd, Westville, vice-president, and Dr. Elbert E. Clark, Danville, secretary-treasurer.

Santa Barbara (Cal.) Medical Society.—This society, long quiescent, was revived and reorganized, November 1, with Dr. Charles Anderson, president; Dr. Charles E. Vaughan, vice-president; Dr. William B. Cunnane, secretary, and Dr. William H. Flint, treasurer.

Corsicana District (Texas) Medical Society.—The annual election of officers of this society, November 4, resulted as follows: President, Dr. John M. V. Wills; vice-presidents, Drs. Clay, Johnson and John E. McClung, all of Corsicana, and secretary, Dr. W. D. Fountain, Venus.

Auxplaines (Ill.) Medical Society.—This society met at Maywood, October 31. Resolutions were adopted making the society a branch of the Chicago Medical Society, and providing that no one shall be eligible to membership in the local body who is not a member of the Chicago organization.

American Roentgen-Ray Society.—The third annual meeting of this society will be held at the Sherman House, Chicago, December 10 and 11. Dr. James B. Bullitt, Louisville, Ky., is secretary of the society, and Dr. Ralph R. Campbell, 414 Marquette Building, Chicago, chairman of the committee of arrangements.

Piedmont (Va.) Medical Society.—At the last meeting of this society, held in Fredericksburg recently, Dr. William H. Lyne, Somerset, resigned as president on account of removal from the jurisdiction. Dr. R. Lee Taliaferro, Madison Mills, was elected president to fill the unexpired term, and Dr. Jesse Ewell, Ruckersville, vice-president.

West Texas Medical Association.—The twenty-sixth annual meeting of this organization was held in San Antonio, October 23. The following officers were elected: President, Dr. Thomas T. Jackson, San Antonio; Drs. Marvin B. Grace, Seguin, and William M. Wolf, San Antonio, vice-presidents, and Dr. Witten B. Russ, San Antonio, secretary and treasurer.

Boulder County (Colo.) Medical Society.—This society met at Boulder, November 6. Dr. Philip H. Keyser, Boulder, read a paper on "The Value of Psychology to the Physician," and Dr. E. F. Talbott, Boulder, made a tabulated report of one hundred consecutive cases of obstetrics. Eight new members were admitted, and six applications for membership were made.

National Association for the Study of Epilepsy and the Care and Treatment of Epileptics.—This society held its annual meeting at the New York Academy of Medicine, November 5. The following officers were elected: Dr. Wharton Sinkler, Philadelphia, president; Dr. William Osler, Baltimore, vice-president, and Dr. William P. Spratling, Sonyea, N. Y., secretary and treasurer.

New York Obstetrical Society.—At the annual meeting of this society, in October, the following officers were elected: President, Dr. Egbert H. Grandin; vice-presidents, Drs. J. Clifton Edgar and George W. Jarman; recording secretary, Dr. William S. Stone; assistant recording secretary, Dr. Howard C. Taylor; corresponding secretary, Dr. Edward E. Tull; treasurer, Dr. J. Lee Morrill, and pathologist, Dr. William S. Stone.

Southern Illinois Medical Association.—This society, at its meeting in Centralia, November 7, after a spirited discussion on the kind of legislation needed, appointed a committee to assist the Illinois State Medical Society in pushing the bill to divorce the control of physicians from the state boards of health on the ground that the present board has too much to do and that a special examining board is needed. Dr. James A. Helm, Metropolis, was elected president; Dr. Edgar E. Fyke, Centralia, secretary, and Dr. Alexis T. Telford, Menard, treasurer. The society will meet in Marion in November, 1903.

British Medical Association, Halifax Branch.—This branch of the association, which was organized in 1887, met at Halifax, October 15, when the following officers were elected: President, Dr. George M. Campbell; vice-president, Dr. Frederick W. Goodwin; secretary, Dr. C. Dickie Murray; treasurer, Dr. Antony I. Mader. Surgeon-General Thomas F. O'Dwyer, A.M.S., was appointed representative on the Council and Parliamentary Bills Committee. The next evening will be devoted to military surgery, when Dr. Carleton Jones, who has recently returned from South Africa, will read a paper on the work done by the Canadian Field Hospital Corps during the latter part of the late war.

Gallia County (Ohio) Medical Society.—This society, at its regular meeting, November 6, was entertained by the staff of the Ohio Hospital for Epileptics, in the pathological laboratory of the hospital. The following program was offered, together with an exhibition of patients and practical laboratory demonstrations: "A Case of Epilepsy and Hemiplegia, Presumably of Syphilitic Origin," by Dr. Harry S. Allen; "A Case of Chronic Lead Poisoning, with Remarks on Saturnine Epilepsy," by Dr. W. C. Gill; "Remarks on Hypernephroma or Adrenal Tumor of the Kidney," and "A Survey of Recent Laboratory Methods for the Diagnosis of Hydrophobia," by Dr. A. P. Ohlmacher, and "Demonstration of the Widal and Diazo Reactions," by Theodore L. Chadbourne.

THE SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Fifteenth Annual Meeting, held in Cincinnati, Nov. 11-13, 1902.

Under the Presidency of Dr. W. E. B. Davis, Birmingham, Ala.

Hypertrophy of the Prostate.

Dr. N. P. DANDRIDGE, Cincinnati, was convinced that the field of usefulness for prostatectomy, when used with discrimination, was large. He strongly urged the necessity of not being carried away by operative furor, which might lead to the same excess which a few years ago characterized the surgery of the ovary, an excess which was now followed by a marked recoil.

Conservative Operations on the Ovary.

Dr. L. H. DUNNING, Indianapolis, reported his experience with more than 100 operations. He employed the method of incising small single cysts, and hematomata, removing the lining membrane, trimming away the redundant portion of the outer wall of the cyst and joining the edges of the incision by a running stitch of fine catgut. In a few instances he used the thermocautery to check hemorrhage, and in other instances he punctured several small cysts and dropped the ovary. He reported gratifying results in 80 per cent. of cases. After a few trials he rejected conservative methods in pus cases, and in cases in which there were numerous small cysts in all parts of the ovary. He found conservative work unsatisfactory in sterile married women, and in interval appendicitis operations in which there was a markedly cystic right ovary. In his series there were known to be 6 cases of pregnancy in which the

patients were happy mothers, and there was a group of 10 cases in girls and young women from whom he had extirpated an ovarian tumor from one side, and had done a conservative operation on the other ovary with a large measure of success.

Even should a considerable per cent. of failures to cure appear, the writer would continue to do conservative work. He believed that the reason we are not able to select our cases was that cystic degeneration of the ovary is a progressive disease, the limits of which one is not able at present to predict. He hoped that with our increasing knowledge we would be better able to select the curable cases for operation.

DISCUSSION.

Dr. GEORGE H. NOBLE had done considerable conservative work on ovaries in such cases as the author had mentioned, and he was satisfied that it was the proper thing to do.

Dr. HENRY T. BYFORD said that formerly ovaries were removed extensively by gynecologists, and that now there was a sufficient number of cases on record to determine what effect the removal of the ovaries had in young people. He recalled quite a number of cases from whom he had removed the ovaries, the operation having produced no harm or mental effect. In many of the cases the women had been in better health since the operation. Conservative operations, if aseptically and properly done, should be followed by good results, without necessarily removing the ovaries.

Dr. WALTER P. MANTON began conservative work on the ovaries several years ago, and he found that in the majority of instances he was successful in relieving the symptoms. However, he had had a few unsuccessful cases which led him to be skeptical in regard to the good work which he might have done formerly. Resection of a cystic ovary or the puncture of cysts of the ovary, followed by swabbing with carbolic acid and alcohol, and sterile water, give satisfactory results.

Dr. GEORGE J. ENGELMANN said all were agreed that it was desirable to leave as much of the tissue as would preserve the sexual activity, and the question arose, How much could be removed and the menstrual function still be preserved, thereby relieving the patient?

Dr. J. G. EARNEST stated that the physician should always make a plain statement to the patient as to what she may expect.

Dr. A. M. CARTLEDGE did not think the association should go on record as advocating the removal of both ovaries in young women simply because they had pus tubes. In every case, he recommended leaving a piece of an ovary, if it is not larger than a grain of corn.

Dr. RICHARD DOUGLAS thought the last speaker had misunderstood the essayist, who did not advocate the removal of healthy ovaries when the tubes alone were affected, but discountenanced the resection of infected ovaries, and with the essayist he agreed in this particular.

Dr. EDWIN WALKER made a plea for more accurate diagnoses, saying that many of these patients suffer from other diseases.

The Surgical Treatment of Pancreatic Cysts.

Dr. A. MORGAN CARTLEDGE, Louisville, Ky., reported two cases, and said that cysts of the pancreas, while rarely encountered, are still the most common pathologic condition of this deep-seated organ that surgeons are called on to treat. The field of surgery of the pancreas should be extended. According to Bückel, the cases treated surgically now number 115. In 99 of those the cyst was opened at the first sitting, with the result that 92 recovered and 7 died. In 16 cases the cyst was opened subsequently, after the formation of adhesions, with 16 recoveries and no deaths. This spoke well for the treatment by incision and drainage. The same author had collected 25 cases where extirpation, either complete or partial, of the sac was practiced, with 4 deaths.

A comparison of the results shown by statistics would seem to indicate that incision and drainage should be practiced as a routine procedure in pancreatic cysts; and yet a closer study of the clinical forms which the cyst may present, together with a closer study into the convalescence of the drained subjects, might cause surgeons to attempt extirpation of the sac more frequently and with better results.

DRS. C. H. MAYO, L. H. DUNNING and ALEXANDER H. FERGUSON mentioned briefly cases they had observed.

DR. RICHARD DOUGLAS said that Mr. Jordan Lloyd had emphasized the fact that there were true and pseudo-cysts of the pancreas. The recent work of Robson, Mayo and others, he thought, had shown the relation between gallstones and pancreatic disease, and it was possible we might have here a true solution of the pathology.

The Curse of Gonorrhea.

DR. JOSEPH TABER JOHNSON, Washington, D. C., followed with a paper on this subject, saying that there is indisputable and overwhelming evidence of a large annual loss of life from specific pelvic inflammation and of a far greater loss of health and power of conception, from the same cause.

From the best statistics he had been able to obtain there are 300,000 women in this country leading lives of prostitution, and the estimate is made by health officers and the superintendents of police in thirty large cities, who made reports on this subject, that for every woman who regularly resides in a house of ill-fame, there is at least one, if not more, just as bad, who never, or rarely, becomes known to the police. This would give half a million at the lowest estimate of candidates for this disease in our country alone.

The chief danger of gonorrhea in the female is the infection of the uterus and uterine appendages. Gonorrhea is the chief source of salpingitis and pelvic peritonitis.

The point on which he laid the greatest emphasis was that gynecologists should be more certain that patients of both sexes are absolutely cured before they are dismissed.

Chronic Appendicitis and Movable Right Kidney.

DR. WALTER P. MANTON, Detroit, called attention to movable right kidney as a factor in the production of chronic appendicitis. In his experience, movable kidney was the most frequent cause of chronic appendiceal disease.

In 200 consecutive cases from his note books the essayist found that the right kidney showed abnormal mobility in 36.5 per cent., and in 65 per cent. a diagnosis of chronic appendicitis was also made. In 22.5 per cent. of this number the diagnosis was confirmed by operation. Among the other cases some were of too mild a type to demand immediate intervention, the patient refused operation, or was now waiting for this to be performed.

Dr. Manton accepted the theory of Edebohls as the most satisfactory yet offered, namely, that the kidney compresses the superior mesenteric vessels between the head of the pancreas and the spinal vertebrae, thus interfering with the circulation in the appendix, and causing congestion and inflammation.

He lays special stress on two points: First, that in obscure abdominal conditions, a diagnosis should not be attempted until movable kidney and chronic appendicitis can be excluded by careful abdominal palpation; and, second, that when nephroptosis and appendicitis are present, operations on the uterus and adnexa will not be followed by cure of the patient unless one or both of these conditions is also removed.

DISCUSSION.

DR. BACON SAUNDERS said his experience had not led him to believe that most of his cases of chronic appendicitis had depended on movable kidney, although the condition may have been overlooked.

DR. EDWIN WALKER had noticed the co-existence of the two diseases, but had not found it common.

DR. ROBERT T. MORRIS had given considerable attention to the association of the two affections, and frequently, where a loose kidney pressed on the superior mesenteric vessels, he had found congestion of the cecum, and on careful palpation, the appendix was found tense; infective appendicitis is more common in such cases.

DR. CHARLES P. NOBLE had operated on 100 cases of movable kidney, and so far as his observation went, he did not think there were more than six in which the appendix was involved.

DR. A. M. CARTLEDGE thought the two affections were more frequently associated than the essayist's statistics showed.

DR. ALEXANDER H. FERGUSON did not think there was any relationship between appendicitis and floating kidney *per se*.

The kidney might be down on the brim of the pelvis and resting on the tip of the appendix without disturbing it.

DR. C. H. MAYO said there was one class of floating kidney which was very movable. One could fix the kidney and obtain a good result, and in some of these he was now removing the appendix at the time the kidney was fixed to determine, if possible, the relationship between the two affections.

DR. W. P. McADORY did not think movable kidney had much to do in causing chronic appendicitis, yet the two conditions might occur frequently at the same time.

DR. GEORGE H. NOBLE, Atlanta, Ga., described a new operation for complete laceration of the perineum, which was illustrated and given in detail in THE JOURNAL, August 9, page 302.

Pregnancy and Labor Following Complete Nephro-Ureterectomy.

DR. J. WESLEY BOYCE, Washington, D. C., in a paper with this title stated that the removal of the kidney had become a frequent operation and no longer excited surprise or comment on the part of the medical profession. It is well understood that removal of a kidney, the function of which has not been previously suspended, entails additional eliminative work on the kidney of the other side. It must be admitted that one kidney is rarely able to perform the functions of two healthy ones, and that any extra taxation on its eliminative powers incident to autointoxication of various forms, is liable to seriously embarrass its functional activity. When nephrectomy has been done for renal calculi, with pyonephrosis or tuberculosis, the same condition is liable to be present, in some slight degree at least, in the remaining kidney. Its function is accordingly interfered with. Various investigators have found a marked toxicity of the urine during pregnancy. Nephritis during this condition is very common. Winckel claimed that 2 per cent. of women, healthy before pregnancy, have albumin in the urine during pregnancy, and, further, that 6 per cent. of all pregnant women have albuminuria. One notable fact in connection with the toxemias of pregnancy, or uremia, is that the amount of urea in the urine is always found markedly diminished. Another important matter is the changes in arterial tension, which vary during and following labor.

He narrated cases and said in conclusion that pregnancy and labor following nephrectomy seriously jeopardize life. Renal complications must necessarily be greatly increased, and therefore induction of premature labor and other treatment of these complications are more often necessitated. The evidence of permanent impairment of the remaining kidney as a result of pregnancy and labor is by no means convincing, but the writer's opinion was that as records are made of such cases, these effects will be apparent.

The President's Address.

This was delivered by the President, Dr. W. E. B. Davis, Birmingham, Ala. He recommended in addition to honorary members, that the Association have another class to be known as life members, to be composed of men of great eminence who were more than 65 years of age, or who had been members twenty years and attended 50 per cent. of the meetings. He suggested that Drs. J. McFadden Gaston, Atlanta; R. B. Maury, Memphis, and Thaddeus A. Reamy, Cincinnati, be recommended by the council for this class of membership. He advised the association to limit its membership to 200, and advised the members to establish a memorial to the association in Birmingham, its birthplace.

He said the national special societies had wielded a wonderful influence in the medical profession, and that medical literature had been enhanced in every way by them, and as individual societies they should be encouraged, but their union into a national congress was not conducive to the best interests of the medical profession. With the adoption of the new plan of organization, providing for a house of delegates to take charge of all business matters in the American Medical Association, more time would be provided for scientific work. He said: "The special societies, composed, as they are, of leaders in the several specialties, are under obligation to the American profession to assist in the better organization of these sections. Many of the members of these societies are officers and active.

working members of the sections of the American Medical Association, and can accomplish this result. There must be one class of membership for the section that can be held by only those who are recognized as teachers and leaders to make membership very desirable and sought after."

He suggested that this class be known as "fellows," to pay in addition to the annual dues of the association, \$5 annually for section dues, which fund would be expended in the publication of the proceedings of the section. The officers and authors of papers should be fellows, but all members could take part in discussion. Thus, an opportunity would be afforded for the ordinary members to show themselves worthy of fellowships. Such an organization of the sections, with volumes of transactions, publishing a list of the fellows, would give stability and a permanency to the section work that could scarcely be had in any other way. With the house of delegates for the general association, and the roll of fellows and association members for each of the sections, it would become the most scientific and influential medical organization the world has ever known.

Dr. Davis paid a tribute to the medical profession of the South, and spoke of McDowell, Sims, and Battey as epoch-makers in surgery. He also referred in glowing terms to the work of Dudley, Paul F. Eve, Warren Stone, Dugas and Pope. Of the many in recent years who had done excellent work, and who were now dead, he mentioned the names of McGuire, Yandell, Briggs, Rogers, Sr., Kinloch, Westmoreland, Sr., Campbell, Gilmore, Nott, Mastin and Richardson.

Memorial To Be Established.

The council presented the following resolution, which was adopted:

Whereas, Dr. W. E. B. Davis, during twelve years of faithful service as Secretary of the Association, declined to draw any salary for his services, expecting in time to establish some suitable memorial of this association with the fund created thereby; therefore, be it

Resolved, That in consideration of this fact \$2000, a sum far less than the salary offered would have amounted to, be appropriated for the establishing of a memorial in Birmingham, Ala., the birthplace of the association; and that this memorial be placed in the Charity Hospital of that city as a ward to bear the name of the association.

New Officers.

The following officers were nominated and elected for the ensuing year: President, Dr. J. Wesley Bovée, Washington, D. C.; vice-presidents, Drs. Bacon Saunders, Fort Worth, Texas, and Christopher Tompkins, Richmond, Va.; secretary, Dr. W. D. Haggard, Jr., Nashville, Tenn.; treasurer, Dr. Floyd W. McRae, Atlanta, Ga. The next place of meeting will be Birmingham, Ala.; the time: the week preceding Christmas, 1903; the chairman of the committee of arrangements: Dr. John D. S. Davis, Birmingham.

(To be continued.)

SOUTHERN MEDICAL COLLEGE ASSOCIATION.

Annual Meeting, held in Cincinnati, November 11.

At this meeting the following medical colleges and departments were represented: University of Tennessee, Nashville; University of Nashville; University of the South, Sewanee, Tenn.; Tulane University, New Orleans; Vanderbilt University, Nashville, Tenn.; Fort Worth University, Texas; Medical College of Virginia, Richmond; Tennessee Medical College, Knoxville; Medical College of Alabama, Mobile; Birmingham Medical College, Ala.; University College of Medicine, Richmond, Va.; Dallas University, Texas.

Resignation of Memphis College.

The most important business of the meeting was the consideration of the resignation of the Memphis Hospital Medical College of Memphis, Tenn., which was formally presented, and on motion, accepted. There have been differences between the main body and this college for some time that have caused serious friction. The most serious cause of disagreement was regarding the length of the course of study in this school and its indifference as to preliminary requirements.

Dr. J. S. Cain, chairman of the Executive Committee, in making his report recommended that the Memphis Hospital Medical College be permitted to withdraw from the association, because of unwillingness on the part of that school to be governed by the laws of the association.

The Memphis college usually has about 600 students, but the sentiment was practically unanimous regarding the acceptance of the resignation.

The secretary reported that only a few of the twelve colleges constituting the association had any beneficiaries, and that none of them had more than twelve, which is the maximum number that any college is allowed to take during any one session. Under this law a beneficiary is one who pays any amount less than the published rates.

Next Meeting in New Orleans.

At the afternoon session two minor amendments to the constitution were adopted, and the by-law fixing the time and place of meeting was suspended as to the next meeting, which will be held in the St. Charles Hotel, New Orleans, May 4, 1903, just prior to the meeting of the American Medical Association.

The President's Address on Preliminary Educational Requirements.

At the afternoon session Dr. Christopher Tompkins made the presidential address. It was endorsed by a vote of the association and recommended for publication. With the omission of the introduction it appears below:

After devoting some considerable thought to the subject, I am struck with the fact that the preliminary entrance requirements of the Southern Medical College Association are themselves very uncertain. It is, as you know, that of a first grade public school teacher. This I find to be quite different in the different states represented by colleges in this assembly, and indeed is not always the same in all parts throughout the same state. It depends largely on the examiner and still oftener on the custom, which happens to be very different, so that colleges in the various states represented in this association will often be able to take some of those students who in a neighboring or distant state would have to be refused by other colleges of the same association, and vice versa.

COMPARISON OF THE TWO ASSOCIATIONS.

The preliminary educational requirements of the American Medical College Association are apparently better fixed and bear more evenly on the schools than do ours. Their educational requirements in the letter of the law are undoubtedly higher than ours and it would appear at first sight that their students ought to or would be obliged to have a better preliminary education. However, this is not always the practical working of the system, as has often been impressed on every dean now present and doubtless also on those belonging to our association who are unable to be with us at this meeting. Who of us has not been called on to matriculate a student or students, from some of the northern or western schools, who has attended one or more courses of lectures and who it is very apparent has not the educational requirements not only of what is commonly known as a first grade public school teacher, but even that of a second grade public school teacher. The reason of this is that whereas the fixed requirements are high and rigid the schools themselves are permitted to examine their own students. I refer to those who can not at the time (and the number of such students is necessarily very large) furnish written evidence of such education.

In the world in which we live human nature is weak, and it is not a thing to be surprised at that very often an incompetent student who wants to be matriculated is matriculated and "conditioned," and the next fall when he offers for matriculation again, his supposed work in academic studies, taken along with his medical studies, puts him in a position when examined by the school that will enable him to go on and finish his course in medicine there or elsewhere. Our own constitution and by-laws do not permit us to examine students and pass on their preliminary requirements; on the contrary, the examination is required to be done by an outsider. See Article 4, Section 3, which reads as follows:

He must possess a diploma of graduation from some literary or scientific institution of learning, or a certificate from some legally constituted high school, general superintendent of state education, or superintendent of some county board of public education, attesting that he has been regularly examined and is possessed of at least the educational attainments required of first grade teachers of public schools or a certificate that he has passed the entrance examination to a university; and a student may be given one month, from the date of his admission to submit his certificate of qualification.

By this means our students must be up to the mark according to the law in the states in which they live. I therefore maintain that in spite of the written letter of the law requiring an undoubtedly higher preliminary education by colleges members of the American Medical College Association, these requirements, because of the manner in which they are ascertained, are liable to and do often, in fact, permit students of inferior education to enter their schools, students who would have to be and are refused by us.

At the last meeting of the American Medical College Association, held at Saratoga Springs, a motion was made to prohibit from membership in that association schools which themselves examine students applying for matriculation as to their preliminary education. This resolution was promptly voted down, showing what is to be their continued policy. In view of these facts would it not be proper for this association to consider some way or means of relieving the southern schools of the criticism of being opposed to higher preliminary academic education and at the same time endeavor in some way to rid ourselves of this undoubtedly unjust criticism. Before dismissing this subject I wish also to say something of the wording of Article 4, Section 3, already referred to.

THE LEGAL INTERPRETATION OF THE REQUIREMENT.

At a glance any one who will take the trouble to read the rule therein laid down will plainly see that it is intended to require of students applying for matriculation in medical schools as a preliminary education that of or equivalent to a first grade public school teacher. This is the particular and essential part of the section and that none who have beyond question such an education can or ought to be refused or barred admission. Such applicants, if properly qualified, if refused, in my opinion, could resort to the courts and compel admission and perhaps sue such schools for damages. After stating the broad fact that the education of a first grade public school teacher is required, there follow certain ways of determining what is at least a first grade public school teacher's education.

How any one could think that the examinations, degrees or certificates named are the only ways that such a fact could be ascertained is passing strange. Still, that has happened. I have myself obtained from the office of the Superintendent of Public Instruction an opinion as to what would in the State of Virginia constitute such an education and when a proposed student presented such written credentials I have always taken him, although these credentials may not have been identical with those suggested or mentioned in the section referred to. The matter as I understand it is referred to the superintendent of public instruction of the state in which the college is situated and what that office determines is a first grade public school teacher's education in that particular state can in no way be gainsaid. He is required to say that certain people "have been regularly examined and are possessed of, at least, the educational attainments of a first grade public school teacher." He is not required to examine them himself and is at full liberty, if he chooses, to accept an examination held by some one else. In order to avoid all question or controversy on this subject I would be glad if the association, if in its wisdom it thinks proper and desirable, takes up and passes on this matter and makes the law, if possible, even more plain than it now already is.

THE B.A. DEGREE.

At this point it would be well to say something of that part of our constitution and by-laws referring to advanced standing. See Article 4, Section 5:

The following classes of students may apply for advanced standing and obtain it, provided every applicant undergoes a satisfactory examination on every branch below the class desired to be entered:

- a. Graduates of dentistry, of pharmacy, and of veterinary medicine.
- b. Graduates and matriculates who have completed one or more courses in colleges of homeopathy and of eclectic medicine.

c. Graduates of recognized colleges and universities who have completed therein prescribed courses in elementary branches of medicine, including chemistry and biology.

The American Medical College Association has practically stricken from their constitution and by-laws this entire section and are striving to make the B.A. degree the preliminary requirement for medical study. In order to help the schools do this, a large number of the great universities of the North, and I think of the West also—and more recently the University of Virginia—have decided and published that they will hereafter allow students to count for the B.A. degree the studies of the first year in medicine. If that course is taken at the same university where they have received their previous academic education, it thereby enables a student or students to get an academic degree at the university and at the same time be advanced one year in medicine. This I regard as a great educational advantage and one that students in general ought to avail themselves of, especially as the first year in medicine can be readily taught away from the surroundings of large cities. It would, of course, cause many young men to take their first year of medicine away from the medical school in which they would eventually graduate. This, however, is a sacrifice that might be desirable for the medical schools to make for the general good. The more especially is this true, as you doubtless already know, that many of our best medical and surgical associations require an academic degree or its equivalent as well as a medical degree before a candidate is allowed to apply for membership in these associations.

Need of Uniformity in Medical Laws.

Dr. J. S. Cain's address was on the question of amalgamation of the two associations. A study of the environments had forced him to the conclusion that there is still a peculiar work for the southern association to accomplish in its individual capacity.

Dr. Bacon Saunders set forth the advantages resulting from organizations, or confederations of medical colleges.

In discussing these addresses, Dr. G. C. Savage suggested that the Confederation of State Boards of Medical Examiners could do much in establishing and maintaining a high standard of medical education. As is well known, one great object of this confederation is reciprocity; but before this can be accomplished there must be uniformity of medical laws. This confederation should establish the minimum preliminary requirements, and should also define a reputable medical college, and only graduates of such schools should be permitted to practice in any state. This would sound the death-knell of cheap-John medical colleges. When that day arrives there will be need for but one medical college association.

Election of Officers.

The following officers were elected for the ensuing year: President, Dr. Christopher Tompkins, Richmond, Va. (re-elected); vice-president, Dr. Bacon Saunders, Fort Worth, Texas; secretary and treasurer, Dr. G. C. Savage, Nashville; and executive committee, Drs. John S. Cain, Nashville, Lewis C. Morris, Birmingham, Ala., and Charles A. Mohr, Mobile.

THE INTERNATIONAL TUBERCULOSIS CONFERENCE.

Held at Berlin, Oct. 23-25, 1902.

The Secretary of State, Count v. Posadowsky, in the Chair.

The German system of insurance against disease, disability and old age among the working classes, which is participated in by the working people themselves, their employers and the state, early compelled the recognition of the advantages to be gained by sanatoria for the treatment of curable diseases, especially tuberculosis. Consequently Germany took the lead in organizing such institutions and has led the way for the whole world to follow in this line. When an international central headquarters for the struggle against tuberculosis was decided on, Germany took the lead for this reason and the international central committee fixed its offices at Berlin. It was even expressly stated in the by-laws that the foreign members of the committee "must reside in Berlin." This last clause was stricken out at the recent meeting and a resolution was adopted that foreign members of the committee

would be reimbursed for their expenses when summoned to an official conference. The International Tuberculosis Conference held at Berlin in October was the first official gathering of the members of the supreme council of this international central bureau organized at the Antituberculosis Congress at London last year. Each country sent its delegates to describe what has been accomplished in the way of general prophylaxis and learn the work being done in other lands. About 100 members were present, a notable gathering of men of wide renown, but only one American, Dr. Eager, representing the Marine-Hospital Service, stationed at Naples.

Transmissibility of Bovine Tuberculosis to Man.

There were only a few strictly scientific communications and no new ideas were presented, the main interest centering in the discussion as to the transmissibility of bovine tuberculosis to man. Each side was more positive in its assertions than ever, Koch maintaining still more emphatically the rarity of such transmission in view of the fact of the almost universal opportunities for it. He also affirmed that boiling does not destroy the bovine tubercle bacillus. The arguments for the intercommunicability of bovine and human tuberculosis by Nocard, Baumgarten, Arloing and others have been reviewed in THE JOURNAL during the last few months and no new facts were adduced except those previously published. Koch reiterated that the sole danger of tuberculosis resides in the patient.

Necessity of Isolation.

B. Fraenkel declared that the prophylaxis of tuberculosis depends on the isolation of tuberculous subjects, proclaiming that the most robust person would inevitably contract tuberculosis if a virulent culture of Koch's bacilli were subcutaneously injected. On the other hand, the most poorly nourished and predisposed subjects would never have the disease if absolutely protected against all contact with the bacilli.

Model Sanatoria.

Some of the model German sanatoria were inspected and aroused enthusiasm. The halls of the Parliament buildings, where the meetings were held, were devoted to an exposition of appliances and measures connected with the campaign against tuberculosis.

Calmette of Lille described the active crusade being carried on in his region by special tuberculosis dispensaries, supervision of the patients in their homes and an educational propaganda by workmen trained for the purpose. A house-to-house crusade is carried on and the rooms of each consumptive when located are washed with chlorid of lime and whitewashed at regular intervals, while the patients are supplied with clothing, bedding, cuspidors and a quart of lysol every week, and steam laundering is supplied at a low rate. The children are sent to a seashore sanatorium. The fact is especially impressed on the consumptives that their sputa is as dangerous to themselves as to those around them as possible sources of new infection. These measures have been applied at Lille for nearly two years, and the results have surpassed all expectations. Numbers of the tuberculous subjects supervised for one to nine months have been clinically cured and resumed work. The expense is borne mainly by private contributions. Italy is introducing a similar system of dispensaries and home supervision. The Norwegian delegate said that compulsory notification of cases of tuberculosis had been enforced since Jan. 1, 1901, and that it had proved feasible and not disturbing. The delegate from Belgium, Dr. Van Rynn, cited the experience at New York as confirming the benefits of notification.

Brouardel of Paris was appointed chairman of the international central committee, which is to meet every spring. With him are associated Andvord of Christiania, Broadbent and Raw of London, Dewez of Mons, Espina y Capo of Madrid, Fraenkel, Althoff and Von Leyden of Berlin, Linroth of Stockholm, Maragliano of Genoa, Scherwinsky of Moscow, Von Schrötter of Vienna, Calmette of Lille, Chyger of Budapest and Rördam of Copenhagen. Pannwitz of Berlin is the general secretary. The second conference will be held at Paris in 1904.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Cyclic Vomiting.

Le Roy, in *Ther. Gaz.*, states that he has tried almost every known measure and drug in these cases and he has obtained the best results from the following combination given at the beginning of the attack:

R. Pulv. aloes et myrrh	3ii	8
Pulv. guaiaci	5iiss	6
Pulv. capsici	5i	4

M. By triturating in a porcelain mortar to an impalpable powder and add a few drops of the oil of cinnamon. Fiant capsulae No. xxiv. Sig.: One capsule every four hours until the bowels move freely.

Hemorrhage from the Nose or Throat.

The following combination is of great service in checking severe forms of epistaxis either from eroded vessels when the cartilaginous portion is destroyed or following operations on the nose or throat:

R. Acidi tannici	3iv	16
Acidi gallici	3iii	12
Glycerini	3ii	8
Aq. destil.	5i	30

M. Sig.: To be used locally by means of a swab or saturate a piece of sterilized gauze and introduce into the nares anteriorly or through the nasopharynx.

Bronchitis from Adenoids.

Méry, according to an abstract in *Amer. Med.*, states that the inflammation of the nasopharynx which exists in patients suffering from adenoids may spread to the bronchi and give rise to a severe bronchitis, accompanied by signs of emphysema. The curative treatment is removal of the adenoid vegetations. He recommends the following medication in addition:

R. Syr. ipecac.	3iiss	10
Sodii benzoatis	gr. xv	1
Sodii bicarb.	gr. viii	50
Syr. polygala (senega)	5v	20
Decoct. polygala	5iv	120

M. Sig.: One teaspoonful every hour.

Mustard poultices should be applied to the chest and hot drinks given; morning and evening a small quantity of the following pomade should be introduced into the nares by means of an applicator:

R. Acidi borici	5i	4
Resorcin	gr. iii	20
Vaselini	5i	30

M. Sig.: Apply locally. The patient's mouth must be closed; he will then draw the pomade through the nose. Instead of the introduction of the foregoing a few drops of mentholated oil, 1 to 100, may be used in the form of a spray. Later stimulating expectorants such as terpin hydrate in doses of one-half to one grain will be of use.

During convalescence one to two teaspoonfuls of the following may be taken every morning:

R. Sulphuris sublim.	3iiss	10
Mellis rosæ	3iii	90

M. Sig.: One to two teaspoonfuls in the morning.

Bronchitis and Rhinitis.

H. C. Howard of Champaign, Ill., recommends the following antiseptic combination in the treatment of different affections of the bronchial passages:

R. Formalin	3ii	8
Spts. chloroformi.	5i	4
Alcoholis	5i	30
Ol. geranii	m. xx	130

M. Sig.: To be dropped on absorbent cotton and inhaled several times a day. This may be carried around in one's pocket in a small tin box containing absorbent cotton saturated with the solution, as recently suggested by the Chicago

Department of Health. The effects of the formalin on the mucous membranes can be quickly detected, and its antiseptic value can not be doubted.

Infantile Bronchitis.

Debove, in *Prog. Medical*, recommends the following:

R. Syr. lactucarii 5v 20|
Syr. adianti,
Syr. papaveris (poppy), āā.....5iiss 45|

M. Sig.: From four to six teaspoonfuls daily; or:

R. Syr. lactucarii 5v 20|
Syr. belladonnæ
Syr. aurantii flor., āā.....3ii 8|
Syr. tolutani 5i 30|

M. Sig.: From four to six teaspoonfuls daily.

Chronic Bronchitis.

The following combination is recommended by E. Fletcher Ingals to relieve the cough in chronic bronchitis when opiates are not contra-indicated.

R. Morph. sulph. gr. i 06
Ammon. carb. gr. xxx-xl 2-2 65
Syr. pruni virg.
Mist. glycyrrhizæ comp., āā.....5iv 16|

M. Sig.: One teaspoonful in water to relieve the cough; or:

R. Terpin hydratis gr. ii 12
Ext. cannabis ind. gr. 1/20 003
Codeinæ gr. 1/8 008
Ol. menth. pip. gtt. ss 03
Sacchari albi gr. iii 20|

M. Ft. capsula No. i. Sig.: One every four hours until the cough is relieved.

Pneumonia.

E. Aufrecht, in *Nothnagel's Encyc. of Med.*, states that he uses quinin and iron in every case. For adults he prescribes the following:

R. Quininæ hydrochlor. gr. xv 1|
Ferri sulph. gr. xlv 3|
Pulv. glycyrrhizæ rad. gr. lii 3/50|

M. Ft. capsula No. xl. Sig.: Two capsules twice a day.

For children he recommends the following:

R. Quininæ hydrochlor.
Ferri sulph., āā.....gr. xxii 1/5
Pulv. glycyrrhizæ gr. xv 1|
Ext. glycyrrhizæ q. s.

M. Ft. pil. No. xxx. Sig.: Take two or three pills daily, according to age.

Burns.

Biddle, in *Penn. Med. Jour.*, states that 50 per cent. of the deaths following burns is caused by the shock. He recommends keeping the circulation and nerve centers in the best possible condition. To do this he advises strychnin, digitalis, whiskey, and aromatic spirits of ammonia in full doses with a good nutritious diet. In order to control the pain and delirium and to procure the necessary amount of rest he recommends the following:

R. Pot. bromidi gr. xx 1/30
Chloralis hydratis gr. vi 35
Elix. simplicis q. s. ad.....5ss 15|

M. Sig.: To be taken at one dose and repeated as necessary.

Normal Saline Solution.

Heinick, in *Med. Age*, states that the employment of the normal saline solution as an infusion is as specific in its field of usefulness as any drug at our command. It can be prepared easily and with sufficient accuracy by dissolving a teaspoonful of salt in a pint of sterilized water. He recommends it in the following conditions:

As an inexpensive cleansing spray in chronic hypertrophic rhinitis.

In diphtheria great relief is obtained by using a hot, normal salt solution in the form of an irrigation.

In skin grafting and to douche the skin grafts previous to transplanting them the saline solution should be used.

As an irrigating fluid for wounds, to irrigate the urinary bladder, and in diarrheal conditions it can be used per rectum intravenously or subcutaneously.

In speaking of the use of the normal salt solution in cystitis, the following formula may be used advantageously in infections of the bladder:

R. Formalin m. vi-x 35-65
Sodii chloridi 5i 4|
Aq. destil. q. s. 3xvi 500|

M. Sig.: To be used in irrigating the bladder, preferably with a double flow catheter.

It is used also in the treatment of burns, in shock or collapse from large hemorrhages and as a vehicle for nutrient enemata. In administering it per rectum a long rectal tube should be introduced after a cleansing enema and elevation of the bed. In giving it subcutaneously a region should be selected where the cellular tissue is loose and easily distensible, such as the axilla, the buttocks, the subscapular region or the abdominal wall. The site of the injection must be thoroughly sterilized as well as the receptacle containing the solution, and it should be introduced at a temperature of 105 to 115 F.

Gastralgia in Children.

The *Progrès Medical* recommends the following in the gastralgias of children:

R. Tinct. belladonnæ
Tinct. calumbæ
Tinct. arnicæ
Tinct. opii camph., āā 3i 4|

M. Sig.: From five to ten drops in a little sweetened water.

Medicinal Treatment of Tuberculosis.

Errico de Renzi, according to an abstract in the *Interstate Med. Jour.*, states that while not denying the importance of the hygienic treatment of tuberculosis, the medicinal treatment should not be overlooked. He uses ichthyol in his clinic in a great variety of cases, and some of them well advanced. The most notable and most constant effect was the diminution of the bronchial catarrh. This diminution showed itself in the lessened amount of sputum and the partial disappearance of râles. Secondly an increase in weight and an improvement in the general condition was noted. One advantage of ichthyol, according to the author, is that it can be used for long periods of time without unpleasant secondary effects. It may be used with success in cases of threatening or actual hemoptysis on account of its vasomotor-constrictor effects. He believes that this preparation should be given a thorough trial in all cases not too far advanced.

The following formula is recommended:

R. Ichthyol 5iiss 10|
Aq. menth. pip. 5iiss 75|
Syr. aurantii 3v 20|

M. Sig.: During the first week one teaspoonful in a glass of water is given daily, half being drunk in the morning and the remainder in the evening. During the second week two teaspoonfuls in two glasses of water are given daily. The dose is gradually increased in this manner until drams two (8.00) are taken daily.

Ichthoform may be substituted, given in powders of grains one and a half (.09) to grains four and a half (.30), ten powders being given daily. Its action resembles very much that of ichthyol and seems to have a more favorable effect on the bowel disturbance, which frequently accompanies tuberculosis, making a greater ingestion and assimilation of food possible.

He recommends sodium salicylatis for its antipyretic effects, given in doses of grains fifteen (1.00) followed by a glass of water. From four to eight doses may be given daily. This preparation may be used steadily for months to control the fever, and whenever its administration is interrupted the fever rises.

Medicolegal.

Validation of Imperfect Registration Retroactive.—The decision holding the validation of imperfect registration not retroactive, reported on page 59 of THE JOURNAL of January 5, 1901, has been reversed by the Court of Appeals of New

York; case of *Ottaway vs. Lowden*. Section 148 of Chapter 661 of the New York Laws of 1893 provides, among other things, that: "If any person, whose registration is not legal because of some error, misunderstanding or unintentional omission, shall submit satisfactory proof that he had all requirements prescribed by law at the time of his imperfect registration and was entitled to be legally registered, he may, on unanimous recommendation of a state board of medical examiners, receive from the regents under seal a certificate of the facts which may be registered by any county clerk and shall make valid the previous imperfect registration." The physician by whom this action was brought to recover for medical services had attempted to make registration as required by the statute, and failed; but, assuming that he was correctly registered, he proceeded with the practice of medicine, in the course of which he rendered the services sued for. A short time thereafter he obtained from the regents a certificate which made valid the previous imperfect registration. This validation, it was held, in the decision now reversed, was not retroactive and did not authorize the maintenance of this action. But the court of appeals is persuaded that the statute operated to give life to the imperfect certificate from the date of its filing, and hence authorized the physician to recover for all services rendered after its filing, and freed him from the various misdemeanors as well. It says that the object of the comprehensive statutes of which the section quoted from forms a part is not to provide a trap for the bona fide and competent physician who, through inadvertence or ill advice, fails to secure a perfect registration, but to shut out from the practice of medicine those whose lack of knowledge of the human body and ignorance touching methods of treatment render their attempts to make diagnosis and prescribe treatment a menace to society. Not only is the standard very high for those who are admitted to the practice of the profession by the authorities of this state, but the statutes attempt to guard against any practicing in this state by unskilful and improper practitioners coming from sister states, showing throughout an intent on the part of the legislature to protect the people from imposition by the unlearned and unskilful who may nevertheless obtain from institutions in other states diplomas purporting to assure competency. To that end the certificate of the board of regents, based on the unanimous recommendation of a board of medical examiners, is exacted, and the requirements of license and registration are insisted on, and not for the purpose of bringing within the penalties of the statutes a physician coming from another state, possessed of all the qualifications which the statutes require. As experience teaches that mistakes are sometimes made in attempting to comply with statutes—especially by those whose training may be in other directions than the law—the legislature has undertaken to provide a method by which imperfect registration may be corrected by the same authorities who acted in the first instance; and as the object of the section authorizing the correction is only to make such corrections as are due to "some error, misunderstanding or unintentional omission," there is no good reason why the legislature should not provide that the correction shall operate as of the date when the "imperfect registration" took effect, thus wiping out the penalties which the statute imposed to better secure its enforcement. And the phrase, "shall make valid the previous imperfect registration," as it seems to the court, when considered in connection with the general scheme of the statute, and the fact that all of the applicant's proofs must go to show that he was entitled to be registered at the time of his imperfect registration, means that that which was once imperfect and invalid shall become perfect and valid as of the beginning.

England and Wales—Midwives' Act, 1902.—In this act, which is entitled "An act to secure the better training of Midwives, and to regulate their practice," it is provided, among other things, that the president of the council shall take steps to secure the formation of a central midwives' board, which shall consist of: 1, four registered medical practitioners, one to be appointed by the Royal College of Physicians of London, one by the Royal College of Surgeons of England, one by the Society of Apothecaries, and one by the Incorporated Midwives'

Institute; 2, two persons (one of whom shall be a woman) to be appointed by the president of the council; 3, one person to be appointed by the Association of County Councils; 4, one person to be appointed by the Queen Victoria's Jubilee Institute for Nurses, and 5, one person to be appointed by the Royal British Nurses' Association. The duties and powers of the board shall be: 1, to frame rules regulating their own proceedings, the issue of certificates and the conditions of admission to the roll of midwives, the course of training and the conduct of examinations and the remuneration of the examiners, the admission to the roll of women already in practice as midwives at the passing of this act; regulating, supervising and restricting within due limits the practice of midwives; deciding the conditions under which midwives may be suspended from practice; defining the particulars required to be given in notifications of practice; 2, to appoint examiners; 3, to decide on the places where, and the times when examinations shall be held; 4, to publish annually a roll of midwives who have been duly certified under this act; 5, to decide on the removal from the roll of the name of any midwife for disobeying the rules and regulations from time to time laid down under this act by the Central Midwives' Board, or for other misconduct, and also to decide on the restoration to the roll of the name of any midwife so removed; 6, to issue and cancel certificates. And generally to do any other act or duty which may be necessary for the due and proper carrying out of the provisions of this act. Rules framed under this section shall be valid only if approved by the Privy Council, and the Privy Council, before approving any such rules, shall take into consideration any representations which the General Medical Council may make with respect thereto. Any woman thinking herself aggrieved by any decision of the Central Midwives' Board removing her name from the roll of midwives may appeal therefrom to the High Court of Justice within three months after the notification of such decision to her; but no further appeal shall be allowed. A copy of the roll of midwives, purporting to be printed by the authority of the board or to be signed by the secretary to the board, shall be evidence in all courts that the women therein specified are certified under this act; and the absence of the name of any woman from such copy shall be evidence, until the contrary be made to appear, that such woman is not certified under this act. Every council of a county or county borough throughout England and Wales shall be the local supervising authority over midwives within the area of the said county or county borough. It shall be the duty of the local supervising authority: 1, to exercise general supervision over all midwives practicing within their area in accordance with the rules to be laid down under this act; 2, to investigate charges of malpractice, negligence or misconduct on the part of any midwife practicing within their area, and should a prima facie case be established, to report the same to the Central Midwives' Board; 3, to suspend any midwife from practice, in accordance with the rules under this act, if such suspension appears necessary in order to prevent the spread of infection; 4, to report at once to the said board the name of any midwife practicing in their area convicted of an offense; 5, during the month of January of each year, to supply the secretary of the Central Midwives' Board with the names and addresses of all midwives who, during the preceding year, have notified their intention to practice within their area, and to keep a correct copy of the roll of midwives, accessible at all reasonable times for public inspection; 6, to report at once to the Central Midwives' Board the death of any midwife or any change in the name or address of any midwife in their area, so that the necessary alteration may be made in the roll; 7, to give due notice of the effect of the act, so far as practicable, to all persons at present using the title of midwife. The local supervising authority may delegate, with or without any restrictions or conditions, as they may think fit, any powers or duties conferred or imposed on them by or in pursuance of this act to a committee appointed by them and consisting either wholly or partly of members of the council. A county council may delegate, with or without any restrictions or conditions, as they may think fit, any power or duties con-

ferred or imposed on them by or in pursuance of this act to any district council within the area of the county, and the powers and duties so delegated may be exercised by a committee appointed by such district council and consisting either wholly or partly of members of the district council; and women shall be eligible to serve on any such committee. This act also contains provision, among other things, against the use, after April 1, 1905, under penalty, of the name or title of midwife by any woman not certified under this act; that, after April 1, 1910, no woman shall, under penalty, habitually and for gain, attend women in childbirth otherwise than under the direction of a qualified medical practitioner unless she be certified under this act; no woman certified under this act shall employ an uncertified person as her substitute; the certificate under this act shall not confer on any woman any right or title to be registered under the medical acts or to assume any name, title or designation implying that she is by law recognized as a medical practitioner, or that she is authorized to grant any medical certificate, or any certificate of death or of still-birth, or to undertake the charge of cases of abnormality or disease in connection with parturition. The act also contains special provisions for existing midwives; with regard to fees and expenses; penalty for obtaining a certificate by false representation, and for the wilful falsification of the roll. Except as otherwise provided therein, it is to come into operation April 1, 1903. But it does not extend to Scotland or Ireland. And nothing in this act respecting midwives shall apply to legally qualified medical practitioners.

1. Vasomotor Ataxia.—By this term Cohen understands a fundamental disorder, out of which, through the incidence of varying exciting causes, various syndrome groups may be developed. The cases are characterized by such symptoms as dermographism, vasomotor disturbances like exaggerated blushing, local congestion, angiomas, special sensitiveness to weather, refractive errors, emotionalism, etc. For description of cases he refers to previous communications and to the recent observations of Savill on a subgroup manifesting acroparesthesia and acroasphyxia. Attention is called to the instability of the controlling apparatus of the vasomotor nerves in the defective reaction of the individual toward environmental changes, so that they show on slight provocation various symptoms which in normal individuals require some more pronounced causes. These phenomena depend on irregular and sometimes widely-distributed contractions and dilations of the capillaries and smaller arteries and veins, and may be divided into three classes: 1. Those dependent on extensive relaxation; 2, those dependent on extensive constriction, and 3, those in which the phenomena of both are intermingled. The last is the most common. Graves' disease represents the extreme type from the phenomena of excessive dilation, Raynaud's that of the opposite, though there are many variations between the two, such as urticaria, angioneurotic edema, migraine of the spastic type and migraine of the parietic type, anomalous eruptions, drug idiosyncrasies, hay fever, asthma, intermittent albuminuria, petechia, minute cutaneous angiomas, paroxysmal tachycardia, etc. As definite exciting causes and definite toxico-pathologic mechanisms are determined, definite nosologic groups may be separated, and certain syndromes like those of Graves and Raynaud be made into diagnostic entities. Over and above these—and this is the most practical issue of these observations—there are many vague and ill-defined conditions arising in response to any one of the number of different stimuli, like weather, temperature, etc. They may vary in some individuals at different times and be manifested in the course of various acute and chronic diseases, confusing the diagnosis. With the conception of vasomotor ataxia the symptoms clear up and treatment can be instituted. Hysteria, neurasthenia and epilepsy have a close, but as yet undetermined, relation to the condition. The symptoms of the menopause are essentially vasomotor ataxic in character. Essential vasomotor ataxia is usually congenital, often affecting several members of a family, but sometimes acquired, following disease or accident. The treatment is largely dietetic and hygienic, with such medication and other therapy as the conditions seem to indicate.

3. Kernig's Sign.—Rudolf has examined for this in 162 cases and found it present in a number of conditions and also in healthy individuals. He does not disregard, however, its pathogenic significance, and offers the following conclusions:

"1. Inability to passively extend the knee fully while the thigh is at right angles to the body, i. e., Kernig's sign, was present in over 60 per cent. of all hospital patients examined. 2. Kernig's method is to place the patient in a sitting posture and then extend the knee. A more convenient way of applying the same test is that mentioned by Osler, in which the patient is kept recumbent and the thigh is placed at right angles to the body and then the knee is extended. 3. A procedure having advantages over both of these methods is first to extend the knee fully, then flex the thigh on the pelvis and measure the angle at the hip. Thus only one angle requires to be gauged instead of two, and hyperextension of the hip (showing muscular hypotonus) can be measured. 4. There is a great proneness in meningitis to increased muscular tonus, which is most apparent in the muscles of the neck and in the hamstrings. This hypertonus, occurring in meningitis, is probably due to cerebellar irritation, and conversely cerebellar irritation is probably the explanation of Kernig's sign in meningitis. 5. Inability to extend the knee fully with the hip at right angles to the body, or to flex the hip to a right angle while the knee is extended, occurs in many conditions besides meningitis. Among such conditions are cerebellar diseases and diseases of the upper neurons of the motor tracts, acute eye troubles, disuse of the lower limbs for some days, as in recumbency, local conditions in these limbs as sciatica, arthritis and contractures, old age, etc. 6. When Kernig's sign is well developed in a recently healthy individual who has fever and none of the conditions mentioned, then it is a valuable sign of meningitis, and this is probably, at least partially, in the cerebellar region. 7. For the purposes of greater clinical accuracy, it is urged that writers on this condition express the angle at the knee or hip in degrees, rather than merely mentioning the presence or absence of the sign."

5. **Gastric Fluid.**—Platt criticises the methods used in examining for acid factors in gastric fluid, which he says have suffered as much as other clinical tests from careless writing. He thinks that the ordinary clinical analysis of the gastric fluid may well be limited to the following acid tests: 1. Qualitative, for free acids in general, with congo-red paper; for free hydrochloric acid with Gunzberg's or Boas' reagent; for lactic and other organic acids by the modified Uffelmann's test, using the ethereal extract of the filtered gastric fluid. 2. Quantitative, for the total acidity with phenolphthalein, and for free hydrochloric acid using either the titration method with tropeolin or the more exact though more tedious method by successive Gunzberg's reactions. The organic acids may be estimated in the same solution by continuing the titration with congo-red paper as the indicator. When all the separate acid factors are to be determined, he offers the following plan: In the first place, the results of the qualitative examination should be borne in mind, and the analysis be made to meet the requirements of the actual state. He says it would be well, too, "to include with the other qualitative tests one for the acid salts, the acid phosphates, and this may be conveniently done by Knapp's method. His reagent is the red ferric thiocyanate, obtained by adding to 5 c.c. of water 2 drops of a 10 per cent. solution of ferric chlorid and 5 drops of a 5 per cent. solution of ammonium thiocyanate. To test for the acid phosphates, 1 c.c. of the reagent is placed in each of two test-tubes, and to one of the filtered gastric fluid is added, while to the other is added an equal amount of water. In the presence of acid phosphates the ferric thiocyanate is either entirely or partially decolorized. Presuming, then, that the qualitative examination has shown all of the acid factors to be present, the plan of analysis would be as follows, two samples being used: To a measured specimen of the filtered gastric fluid decinormal alkali is added until a drop of the fluid gives no reaction with Gunzberg's reagent, or, less exactly but more conveniently, a few drops of a saturated alcoholic solution of tropeolin OO may be added to the fluid and then the standard alkali until the magenta or purple-red of the solution turns to a true red (or, in the absence of organic acids, to a yellow). In either case the number of c.c. of alkali used serves for the calculation of the free hydrochloric acid. The addition of the decinormal

solution is now continued until the fluid under titration fails to give a reaction with Congo-red paper (the solution should now have a yellow color) and from the number of c.c. used the organic acids are estimated. A few drops of a 1 per cent. aqueous solution of alizarin are now added and the titration continued until the yellow-brown of the solution turns to violet; from the amount of alkali required to effect the change the acid salts are estimated. Finally, the total acidity is determined in the second sample, using phenolphthalein as the indicator, and from this the free hydrochloric acid, the organic acids, and the acid salts are deducted to obtain, approximately, the amount of hydrochloric acid in proteid combination. As an alternative method we may determine the free hydrochloric acid and the organic acids as above indicated, and then, adding phenolphthalein, continue the titration until the color change is effected. The amount of alkali added after neutralization of the organic acids gives together the acid salts and proteid-combined acid. The total alkali used indicates the total acidity. A second sample may now be titrated with alizarin as the indicator, this giving all of the acid factors with the single exception of the acid in proteid combination. The later may then be obtained by subtracting the results of the alizarin titration from the total acidity."

8. **Congenital Dislocation of the Hip.**—Whitman discusses the methods of treatment of congenital hip dislocation, holding that in certain cases one or more of the cutting operations must supplement the bloodless method, arthrotomy, osteotomy and excavation of the acetabulum, the latter of which is being more and more restricted in its application. He is inclined to the following opinion from experience: That the more complete fixation that may be obtained by carrying the plaster bandage below the knee after reduction, combined in certain instances with lessened outward rotation of the limb, is an improvement on the ordinary technic of the Lorenz operation in the treatment of young children; 2, that a longer period of fixation in an attitude approximating the normal is necessary to assure the remolding of the acetabulum in old subjects; 3, that arthrotomy and osteotomy must be regarded as necessary supplements to conservative treatment; 4, that the original Hoffa-Lorenz operation offers a prospect of a better ultimate result than transposition, and that it must, therefore, be held in reserve as a final resort after failure of the less radical treatment.

9. **Smallpox.**—The causes and treatment of smallpox are discussed by Magill, who holds that it is due to an organism, but he does not, as the title of his paper would seem, to indicate, demonstrate the species. He holds that vaccination rarely confers an immunity of more than eight years' duration, and often not longer than three to five years. He believes in an abortive form of smallpox where the eruption may be absent, though the patient has the intense backache, chills, headache, etc., the symptoms subsiding in three or four days. Examination of the blood of individuals thus affected shows the mononucleosis, specially characteristic of smallpox, and invariably fixes the diagnosis. He also remarks that the specific germ may be carried by a person for some time without its entering the system, which is important when the period of incubation is considered. He says contact is the only means of contagion; that air-borne smallpox is a myth.

11. **Gonorrhea.**—The three cardinal symptoms of gonorrhea, given by Wolbarst, are a profuse discharge, an angry-looking meatus, and a cloudy urine. These, with the finding of gonococci, make the diagnosis complete. He believes in a rather frequent non-specific form of urethritis which may cause confusion in the diagnosis. Other conditions mentioned are syphilis involving the urethra or chancre in that situation. He also recommends the Jadassohn-Goldenberg tests as absolutely reliable and as avoiding the fallacies of the Thompson two-glass test. He thinks it is hardly safe to consider posterior urethritis as a constant complication. The symptoms may be very mild or very severe as the infection may cause inflammation of all the genital organs and bladder, gonorrheal rheumatism, etc., as is well known. He urges the importance of making a correct diagnosis of inflammatory urethral affec-

tions and thinks if physicians would pay more attention to this subject, there would be fewer advertising quacks.

14. Tuberculosis.—The results of the first year's work of the White Haven Sanatorium are given by Flick as proving: 1, that tuberculosis is curable under the most primitive conditions, provided the patient is kept out of doors and given plenty of the right kind of food. The comforts of life are of minor importance, and exposure to the weather and cold may be disregarded. 2. For successful sanatorium work patients should be carefully classified and kept apart according to the class to which they belong. Incipient cases and chronic cases, with a good resisting power and a tendency to recovery, should be kept by themselves, and advanced cases with fever and doubtful as to outcome should be also kept separate. Dying patients should be kept in an institution especially adapted for their comfort and amelioration of distressing symptoms. 3. That tuberculosis is seldom recognized in practice until it is well advanced and more than one important organ involved. A systematic examination of urine has revealed involvement of the kidneys in a surprisingly large percentage. 4. That incipient cases recover in a very short time and advanced cases require a very long time for complete recovery. Inquiry as to the cases after leaving the institution shows that the incipient cases had generally kept well, but the advanced ones had mostly lost ground, while some who have remained in the institution are apparently making good recovery. He gives a tabulated statement of all the cases treated, with their results.

18. Suppurative Tubal and Ovarian Disease.—The following points are emphasized by Williams in the conclusion of his article: "1. That gonorrhea is by far the most frequent cause of suppurative tubal and ovarian disease. 2. That vaginal puncture is dangerous and unsurgical. 3. That the mass should always be removed through an abdominal incision. 4. That plain sterile water should be used in all abdominal operations. 5. The use of mercury, permanganate or any antiseptic, except alcohol, is unnecessary in the preparation of the operator or assistants, as cleanliness is the great point and may be obtained by soap, water and brush, using many changes of water and taking many minutes to scrub. 6. That silk should be used in all tying within the abdominal cavity. 7. That an absolute differential diagnosis previous to operation is in the majority of cases impossible. 8. That the cases in which drainage is used usually do better than those not drained. 9. The absolute avoidance of morphin, or any form of opium, before or after operation. 10. That the objections to operations are not founded on fact and that there is not enough consensus of opinion that these suppurative conditions should always be operated upon."

19. Movable Kidney.—With the symptom of abdominal pain the question of kidney displacement should always be considered. Reed remarks that many cases are not serious as regards results and the symptoms have a very wide range. He describes his method of determining the position of the kidney. The patient should lie on the opposite side to that about to be explored, with the shoulders thrown forward, the thighs flexed, and the flesh bared. The physician should take a position to the rear, placing the tips of the fingers of one hand in the triangular space behind and immediately below the twelfth rib, the fingers of the other hand directly opposite and immediately below the margin of the ribs. The patient should then be instructed to inspire deeply, hold the breath a minute and then let it go quickly. The finger tips of both hands should be thrust in firmly below the ribs rear and front and on expiration be quickly approximated as nearly as possible. In this way if mobility is but normal the kidney can easily be palpated. He thinks the operation should be repeated if not successful the first time. If the kidney has an unnatural mobility, success in palpating it is more certain, for it descends lower with inspiration. This method has been most satisfactory to him. He also describes his operation of nephropexy, not claiming that it is perfectly new. The method he advises embraces the muscle-splitting idea of McBurney to secure primary union rather than healing by granulation. He makes a straight incision, with the patient in the prone position and a large

round cushion under the abdomen, between the twelfth rib and the crest of the ilium along the outer margin of the erector spinæ muscle, splitting rather than cutting the muscle as much as possible. When the kidney is brought into position it is divested of its fatty capsule, much of which is removed. The fibrous capsule is split the full length of the kidney and carefully reflected from the sides to the extent of an inch. Each flap should then be stitched by four or five chromicized catgut sutures to the divided muscle. The suture is not inserted in the edges, but given a deep hold in both muscle and capsule. When the suturing of the fibrous capsule to the muscle is completed, interrupted sutures should be placed through the edge of the muscle and tied, which brings the muscular tissue in apposition to the exposed cortex of the kidney, insuring firm adhesion. The skin may be closed by interrupted silkworm-gut sutures. He suggests care in avoiding the iliohypogastric nerve and in not anchoring the kidney too high; the larger portion should be below the twelfth rib. It should also be kept in its normal relation to the axis of the body to avoid any twist of the ureter. The patient should be kept in bed three or four weeks and in many cases tonic and constitutional treatment begun and continued indefinitely. He suggests that before promising too much from operations for movable kidney, it is well to make sure that there is no general enteroptosis as a cause of the symptoms.

20. Empyema.—Withington analyzes 135 cases with special attention to the bacteriologic findings, the rate of mortality, result of treatment, etc. He thinks in the majority of cases it is the result of pneumonia. The character of the pneumonia is not to be judged by the organism found in the empyema. The great difficulty in securing the healing of operated cases is in bringing the opposite pleural surfaces into permanent contact. This is one reason for the free resection of ribs, and for the relatively favorable prognosis in childhood on account of the greater liability of a soft and flexible chest wall to contract on the lung. The gradual development of pus can usually be predicted with strepto- or pneumococci in the first fluid, but it can occur even with sterile findings. He insists on the importance of differentiating empyema from subphrenic abscess on account of the danger and location of the internal organs. He also advises delay of the thoracotomy till the pneumonia has resolved, keeping down undue compression by occasional aspiration of the pus.

21. Round Shoulders.—Lovett describes four types of spinal curvature: the first is a general curve (an exaggeration of the normal lines); 2, a backward projection greatest in the mid-dorsal region, the seventh cervical and mastoid points forming a straight line above it; 3, the lower part of the back straight and head runs forward from the seventh cervical; and lastly, 4, the spinal points form a nearly or quite straight line. He concludes that the study of faulty position has been incomplete. The spine has alone been considered rather than the relation of the feet, legs and pelvis to the spine, and the relation of the whole body to the perpendicular. The method he here describes is the side elevation of the whole attitude; the relation of the legs, thighs, pelvis and head to each other and to the perpendicular. He says that the seat of faulty attitude is not as yet formulated, and gymnastic treatment should be general and local. His method consists in placing the patient by an upright rod to which a sliding arm has been attached. At right angles to this is another horizontal arm eighteen inches long, placed at six inches from the back surface of the upright rod. The back surface of the upright rod is taken as the perpendicular plane from which distances are to be noted, and the measurements are made from the sliding horizontal arm, which is always six inches distant from the back surface of the upright rod. Any point, therefore, more than six inches from the sliding horizontal arm is in the front of the perpendicular plane agreed on, and any point less than six inches is behind it. The middle of the external malleolus was taken as the lower end of the perpendicular plane, with feet forming an angle of 45 degrees, the patient standing without shoes and in the natural position. He gives numerous photographs and tracings thus obtained.

25. **Epilepsy.**—Thomson deprecates the importance attributed to the convulsive element in epilepsy and points out that it is not characterized by special symptoms. Loss of consciousness is not always present, and he gives cases where it was retained throughout the attack of the graver epilepsies, or where there were alternative attacks of aphasia with perfect retention of consciousness. His definition of epilepsy is that it is a disease characterized by sudden derangement of the normal regulative inhibition existing between the cortical nerve centers, induced in the first place by abnormal afferent excitation, thus shifting the primary seat from the motor to the sensory or afferent portions of the nervous system.

26.—See abstract in *THE JOURNAL* of November 8, p. 1205.

27.—*Ibid.*, October 25, p. 1064.

29.—*Ibid.*, p. 1067.

31. **Pyuria.**—From his experience Guiteras lays down the following principles as to the preliminaries of exploratory incision or operation for pyuria: 1. All the methods at our command should be employed for determining the seat and nature of the lesion, examination of the urine, including cryoscopy and the phloridzin test, cystoscopy, ureteral catheterization, segregation of the urine from each kidney by appliances in the bladder and radioscopy. 2. The examination of the urine should be considered of the utmost importance and never entrusted to any except a competent man. 3. It is possible by careful study of the pus, blood, etc., and especially of the epithelial elements to determine the nature and seat of the lesion in the urinary tract. 4. A renal suppurative lesion being found it must be located in one or the other kidney, which can be done by cystoscopy, urethral catheterization combined with the phloridzin test, followed by an examination of urine from each kidney, the Roentgen rays, and, if need be, exploratory incision. Omission of one or more links in the chain of methods of examination here enumerated may give rise to grave errors in the diagnosis, and nephrectomy is never justified when we are not positive that the opposite kidney is present and in good condition on the basis of the tests mentioned.

32. **Dysentery.**—The treatment of dysentery in Peru is described by Hunter, who usually begins with ipecacuanha, 45 grains, preceded by 15 to 20 drops of tincture of opium and a sinapism to the pit of the stomach. He has also used alkaline solutions to wash out the mouth after vomiting, which is frequently very acid. After the ipecac there is little to be done except to keep the patient at rest and warm in bed and attend to the diet. If there is too much diarrhea treat it, but if the bowels become confined and require an enema, that should be attended to. If the ipecac fails, or is refused, he has employed the salines in some cases, sulphates of magnesium and soda. In some he has used resin of podophyllum, gr. 1/8, with 1/6 of a grain of powdered ipecac until bilious stools are produced. When other remedies fail in acute dysentery he uses turpentine with opium in emulsion, and if the movements continue greenish and slimy he uses lactic acid in dose of 15 minims largely diluted. The above are the principal remedies that he has employed. For drink he would first give the patient boiled water. For the first two or three days there will probably be very little appetite, then he allows chicken soup and arrowroot; afterward stronger diet can be given.

51. **Raynaud's Disease.**—Cushing reports a case of Raynaud's disease relieved by the application of the tourniquet to interrupt vasomotor innervation. The results were good. The treatment he uses is not applicable to cases where the vascular spasm affects territories other than the limbs, but it is deserving of further trial. Its principle seems to depend on the physiologic blocking effect of the elastic constriction on the peripheral vasomotor nerves. The temporary interruption of function allows the terminal arterioles to completely relax, and a state of arterial hyperemia to take the place of the local asphyxia which has resulted from the pre-existing spasm.

59.—See abstract in *THE JOURNAL*, xxxvii, p. 1392.

60. **Toxins in Inflammations of the Eye.**—The Boylston prize essay by Randolph gives the results of experimental studies on the effects of toxins injected into the eyes of rabbits, and closes with the following conclusions: "1. Bacterial toxins, so far as tested, when instilled even for many hours into the healthy conjunctival sac were found incapable of producing inflammation or causing other injury. 2. The same toxins when injected into the tissue of the conjunctiva or into the anterior chamber invariably set up local inflammation, the extent and intensity of the inflammation varying to some degree according to the species of bacterium yielding the toxin. 3. Bacteria which had not previously been proven to produce soluble toxins were found to produce them even in young cultures, and it is suggested that injections of bacterial filtrates into the eye, particularly into the conjunctival tissue, constitute a more delicate biological test for the detection of certain toxins than the tests usually employed for this purpose. 4. The experiments recorded in this paper furnish additional examples, in a comparatively new field, of the importance of toxins in explaining the pathogenic action of bacteria, and likewise emphasize the etiological significance of injuries of the covering membrane of the eye in favoring the action of toxins and of bacteria."

61. **Osteitis Deformans.**—The cases reported by Prince are discussed at some length and quite fully illustrated. He finds, summarizing his results, that: "1. We have no sure ground for differentiating hyperostosis cranii from osteitis deformans. 2. Hyperostosis cranii and osteitis deformans are probably trophic disorders. 3. Various clinical and pathological facts seem to indicate that they are at least allied disorders, and perhaps only different manifestations of one and the same disease. 4. The osteo-arthritis changes so commonly found in osteitis deformans are probably manifestations of the disease, and not complications. 5. The results of autopsies thus far made do not at all exclude the nervous system as the seat of trophic derangement, but the changes that have been found in the spinal cord and peripheral nerves and analogy with other known lesions like those of tabes and syringomyelia, suggest a neuropathic origin similar to that of the myopathies. 6. In future cases the nervous system should be exhaustively studied."

62. **Osteitis Deformans.**—From an examination of cases, skiagrams and specimens, Fitz concludes that hyperostosis is a condition which may affect few or many bones, early or late in life, and with inconstant symptoms; that the evidence in favor of the recognition of an independent disease—diffuse cranial hyperostosis—is insufficient, since the symptoms assigned to this affection are inconstant, and may occur in osteitis deformans.

63. **Suppurative Otitis Media.**—We may lay down the general rule, Dench says, that in any case of primary infection of the ear, if seen early in the acute stage, serious intratympanic caries can be prevented, the only exception being where there is early involvement of the mastoid cells and where there is tubercular infection of the intratympanic structure. Caries or necrosis is the essential or underlying cause of the symptom of chronic otorrhea, and it should be dealt with by the surgeon exactly as he would deal with the same condition elsewhere in the body. Two methods are available: 1. To remove all carious bone through the external auditory meatus. Knowing that in the early stages it is usually confined to the ossicular chain and those parts immediately adjacent to the malleus and incus, it seems reasonable that removal of these bones and curettement of the middle-ear would be an efficient procedure, and there is abundant proof of this fact. It is perfectly possible to remove not only the ossicles, but also any carious bone situated low down in the tympanic vault. Injury to adjacent structures, such as the facial nerve, the jugular bulb, the semicircular canals, the cochlea, and the cranial contents, seldom occurs during the course of this simple operation. In many cases, however, we have to deal with a caries of the middle-ear so extensive that it is impossible to remove all dis-

125. **Empyema of the Sphenoidal Sinus.**—Hinkel has had experience with 20 cases of disease of the sphenoidal sinus, in almost all of which the diagnosis was verified by operation. In only one instance was he sure that the sinus alone was involved, though in 7 others the other cavities were practically intact. The symptoms of the condition are obscure; he tabulates the principal ones he observed. Headache was observed in 9 cases; in 6 it was the most prominent symptom, and in 5 was unilateral. It was usually temporo-parietal; in one case chiefly about the root of the nose; in others pain was complained of behind the eye. In none of the cases was there any abnormality of the visual field or disease of the eye ground, but asthenopia was prominent in 2. Pain in the ears was observed in one case; there had been an otitis which had ceased. Asthma was present in 6 cases, cough in 8, pharyngeal catarrh in 2; in one it was the only symptom. Polypus was associated with disease of the sphenoidal sinus in 7 cases, and in 2 cases there were malignant growths. He describes his method of operation, preferring the intra-nasal route, which is usually not difficult. The possibility of penetrating the cranial cavity is to be considered, but deaths from this cause are few as compared with those due to meningitis from untreated sphenoidal abscess. Immediate or secondary hemorrhage may be serious, but is rare and generally controllable. His results with the operation have generally been satisfactory; the distressing symptoms have been relieved.

126. **Scarlatinal Perforation of the Faucial Pillars.**—Hubbard calls attention to this result following streptococcal angina, which has not been very extensively noticed. He remarks that it rather restores confidence in mankind to find so many causes for throat ulcerations other than syphilis. Special text-books and syphilographers do not give proper credit to scarlatinal angina as a cause of defects and cicatrices in the faucial pillars, but a deep focus of streptococcal infection is a very possible one. Perforation and scarlatinal ulceration is usually bilateral; being often very insidious and marked by other severe systemic symptoms, the lesion is very frequently overlooked. The treatment must be conducted with extreme surgical thoroughness and patient persistence.

129.—This article has appeared elsewhere. See THE JOURNAL of November 15, §33, p. 1283.

133.—Ibid., title 43, p. 1278.

138. **Gall Bladder Disease.**—Allen insists on the importance of early operation in possible gall bladder disease, exclusive of diseased conditions of the stomach, pancreas, etc., and where the diagnosis is positive and medical treatment has been strongly advised. In other cases where the diagnosis is uncertain, whether it be a question of malignancy, stone or inflammation, it is wise, in his opinion, to advise early exploration. If malignancy is encountered little damage has been done. Exploration will often result in the discovery of conditions which can only be helped by further surgery, and the earlier it is undertaken the greater the safety to the patient and the fewer the complications.

FOREIGN.

Titles marked with an asterisk (*) are abstracted below. Clinical lectures, single case reports and trials of new drugs and artificial foods are omitted unless of exceptional general interest.

British Medical Journal (London), November 1.

- 1 *A Discussion on the Causes, Diagnosis, and Principles of Treatment of Dilatation of the Stomach. T. Clifford Allbutt and others.
- 2 *On the Dietetic Treatment of Granular Kidney. Carl von Noorden.
- 3 A Successful Case of Gastroplication for Dilated Stomach. William M. Banks.
- 4 *A Discussion on the Differential Diagnosis of Functional and Organic Paralysis. Thomas Buzzard.
- 5 *Infantillism and Senilism. Hastings Gifford.
- 6 The Cause of Heart Irregularity in Influenza. James MacKenzie.
- 7 The Clinical Estimation of Urinary Purins by Means of the Purinometer. I. W. Hall.
- 8 Observations upon Certain Forms of Arthritis. F. J. Poynton and Alexander Payne.

- 9 Some Practical Remarks on the Diagnosis of Heart Disease. David Drummond.
- 10 The Earliest Known Physician. F. M. Sandwith.
- 11 Overlooked Forms of Graves' Disease. Harry Campbell.
- 12 Some Observations on, and the Results of the Treatment of, 100 Cases of Pulmonary Tuberculosis Treated by the Open-Air Method. D. J. Chowry-Muthu.
- 13 The Dietetic Treatment of Pulmonary Tuberculosis. Noel D. Bardswell and J. E. Chapman.
- 14 Ivory Exostosis of Orbits Operated upon and Observed During Eighteen Years. Karl Grossmann.
- 15 Four Cases of Monocular Neuritis. Charles G. Lee.
- 16 On a Method of Suturing the Tendons to Form a Better Stump After Enucleation of the Eyeball. Simeon Snell.
- 17 A Method of Excision of the Eyeball to Secure Greater Mobility of the Stump. Ernest Clarke.
- 18 A Discussion on the Treatment of Sclero-keratitis. Arthur Sandford.
- 19 The "Sliderphone," a New Instrument for Discovering Iron Splinters in the Eyeball. J. E. Widmark.
- 20 Civilization and Eyesight. Charles Wray.
- 21 *Contribution to the Etiology of Myopia. J. E. Widmark.
- 22 Double Case of Congenitally Displaced Transparent Lens Treated by Discission. David McKeown.
- 23 Notes on Forty Cases of Extraction of the Lens in Cases of High Myopia. Adolph Bronner.
- 24 Vasomotor Disturbance of the Eye. Samuel Lodge.
- 25 Experimental Lesions of the Retina. J. Herbert Parsons.
- 26 A Discussion on the Rarer Forms of Optic Atrophy. James Taylor.

The Lancet (London), November 1.

- 27 The Pathology of Infection. J. Burdon-Sanderson.
 - 28 *The Nature, Causes, and Treatment of Cardiac Pain. Alexander Morison.
 - 29 A Case of Aneurism Involving the Innominate, the Right Subclavian, and the Right Common Carotid Arteries. Charles A. Ballance.
 - 30 *Abstract of Certain Experiments on Tuberculosis. George Dean and Charles Todd.
 - 31 Ozone in Chronic Middle-Ear Deafness. George Stoker.
 - 32 The Epidemic of Cerebrospinal Meningitis at Lisbon. H. W. Seager.
 - 33 Some Clinical Aspects of Revaccination. Arthur Maude.
- Archives Gen. de Medecine (Paris), August.
- 34 *La chlorurie alimentaire expérimentale dans les néphrites. H. Claude and A. Mauté.
 - 35 *Etude cytologique des pleurésies tuberculeuses. F. Barjon and A. Cade.
 - 36 Etude des troubles du langage par lésion de ses centres d'arrêt. (Logorrhées de Pick). R. Touche.
 - 37 *Des accidents qui résultent de l'enfouissement sous la neige (being buried under snow). Ferrier.
 - 38 Poisons, Toxins and Venoms. J. Noé.—Les venins. (Seventh article.)

September.

treatment, systematic rinsing of the stomach and the admin-
istration of water by the rectum. These rules are applicable
until surgical interference is indicated. Atonic dilatation,
however, is the principal thing and is frequently a complica-
tion of ill health from other causes which the stomach ag-
gravates and thus keeps up a vicious circle. He finds liberal
doses of bismuth, with sodium bromid and a little tincture of
rhubarb in a mucilaginous and cordial water very helpful, and
if there is any suspected hyperchlorhydria, the use of calcined
magnesia. If the muscle fiber is suspected to be enfeebled,
strychnin seems to be indicated, but local effects are not im-
mediate. In his experience he has come to expect little from
electricity or from massage unless it is in very skilled hands;
it should not be employed before the third stage of digestion.
Hydrotherapy expertly carried out and not after a routine
fashion is very useful, especially when sleeplessness is trouble-
some. Gentle saline laxatives are useful; the copious use of
water is bad. In case of vertigo he thinks the avoidance of
liquids at meals is undoubtedly a very excellent remedy. Rest
after meals is a good thing and in distended stomach he finds
papain a useful aid in digestion and a little hydrochloric acid
in water unless there is reason to believe that acid is formed in
excess. Meals must be cut down to physiologic standards,
eaten slowly and thoroughly masticated. The teeth should be
carefully examined. It is an important thing to relieve a per-
son from the press of occupation and business. Anemia and
other causes he treats in the usual way.

2. Dietetic Treatment of Granular Kidney.—The ques-
tion of diet in chronic nephritis is discussed by Von Noorden,
who first remarks in regard to an examination of the secretory
and excretory actions. He questions as to how much albumin-
ous substances can be allowed. As regards this point he thinks
that for men about 92 to 112 grams of albuminoids and 80 to
100 grams for women is about the proper amount, if the general
condition is a good one, but in acute exacerbations the quantity
will have to be reduced. This, of course, must not be done
without special reason, because it would weaken the patient.
As regards quality he recognizes no special differences; it is no
special matter which kind of albumin is eliminated, the patient
can be allowed considerable variety and freedom in diet.
The question how much fluid a patient with granular kidney
can be allowed has recently come to his attention. Formerly
it was taught that the patient passed a larger quantity of
urine and accordingly must drink a great deal, but he says we
must not forget that by inundating the vascular system we
increase the work of the heart and heart disease is a constant
accompaniment in chronic nephritis, and may be the more
dangerous of the two. A reasonable reduction of the daily
quantity of fluid, he thinks, has a life-saving effect. He would
not wait until the strength of the heart has given way, but
would tell every person with granular kidney not to drink
more than one and a half liters a day, to guard against cardiac
weakness. It is also important to warn against overeating.
He calls attention to the danger of corpulence in these cases.

4. Functional and Organic Paralysis.—The term func-
tional is here limited by Buzzard to cases of paralysis, which
it would be possible to simulate voluntarily. There are some
symptoms, the presence of which are conclusive as to the exist-
ence of organic disease, such as optic neuritis or atrophy, fixed
pupil, hemianopsia, absence of knee-jerk, electrical reaction
changes, localized atrophies, characteristic bed sores, bladder
paralysis with ammoniacal urine, paralysis exactly limited to
a single nerve region and the toe phenomenon of Babinski.
There are no symptoms which can be relied on, however, un-
supported, to establish the diagnosis of functional paralysis.
He limits his observations to the following forms: hemiplegia,
monoplegia, paraplegia and insular sclerosis. It is very rare
for any kind of functional hemiplegia to have been imme-
diately preceded by apoplexy and the anesthetics are decidedly
different and apt to be only partial. Hemianopsia is not ob-
served in hysterical hemiplegia, but amblyopia with contrac-
tion of the visual field is. The sight affections alone may be
an important guide from this and other symptoms. The
differences in gait are classic in the two forms, and the com-

1. Dilatation of the Stomach.—In opening the discussion
on stomach dilatation, Allbutt says the means of defining the
position and volume of the organ are defective, owing to the
anatomic arrangements. He thinks the dependence of dilata-
tion of the stomach on movable kidney has been overrated. Re-
laxation and extension are apt to occur in acute gastritis and
chronic gastritis, most commonly of all in primary muscle
failure, which may be due to the toxic action or to some atony.
Spasm of the pylorus is claimed to be sometimes strong enough
to cause dilatation of the stomach, and there is surgical evi-
dence for this fact. He thinks also that under certain nervous
perturbations a sort of gastric paresis may occur. He asks
how are we to detect the lesser degrees of dilatation and dis-
tinguish them from mechanical conditions and gastroptosis.
The symptoms may be indefinite. Lassitude, heaviness after
meals, pain at the ninth thoracic vertebra, vertigo, sleepless-
ness, depression, flatulence, cardiac irregularities, scanty urine,
etc. The local signs are noted. Slack stomach is common in
heart diseases and may be simulated by distended colon, and
he remarks in regard to splashing sound, squelches, etc., as
symptoms. The test of the contents of the stomach by siphon-
age is important, but he finds difficulty in practicing this on
British subjects, who do not like this method. Sir William
Jenner called attention to the valuable evidence of seeds or
grit if the time of their swallowing and their passage from the
bowel can be accurately dated. The quantity of water is no
special guide as there are variations of tolerance and the pos-
sibilities of retained gases are very great. It is of more
service to note the force of its return. Gastric illumination
teaches us little, but we learn something from radiography,
and with this the chemical tests, the use of iodid and salol may
be of value. In obstructive dilatation the general rules are of
concentration of diet, with parsimony in carbohydrates as a

bined flexion of the thighs and trunk noticed by Babinski is quite an important distinction. The flaccidity of the limbs instead of contracture is also evidence. The behavior of the reflexes is important, though not an absolute guide. Reappearance of voluntary motion at times is important, but he lays special stress on the Babinski toe phenomenon. The only form of organic monoplegia with which the functional form is at all likely to be confounded is that which depends on the lesser cortical centers or their pyramidal tracts and complete cortical monoplegia is a rare phenomenon as compared with hemiplegia. Functional monoplegia, on the other hand, is not at all rare. The paraplegic form of functional paralysis is probably the most common and the less difficult of diagnosis. Absence of knee-jerk is never a symptom of functional disorder. The electric reaction of the muscles, the condition of the plantar reflex and negative findings supported by the absence of bed sores or bladder involvement ought to help the diagnosis. It will be found that the district occupied by anesthesia does not correspond with that which would be occasioned by organic lesion. Insular sclerosis is noticed at some length, and he does not advocate the view of a hysterical condition eventuating in structural disease. The Babinski toe symptom is of special value in this condition. The difficulty in diagnosis is great in neurotic persons with insular sclerosis, with its occasional transitory paralysis.

5. **Infantilism.**—Gilford describes the various kinds of infantilism, normal infantilism, which simply means the delay of maturity and morbid infantilism associated with disease of the thyroid, pituitary body and sexual organs. He uses the term *ateleiosis* to indicate that form characterized by an abrupt onset, absence of perceptible cause, the presence of infantilism of a conspicuous kind, the retention of unimpaired intelligence and a special tendency to marked delay of the development of the sexual system. It may begin at any of the developmental periods of life and even in the fetal condition. In this case there may be an abnormal smallness of the brain and actual imbecility. It is most characteristic when it appears during infancy and childhood. The childlike form and physiognomy added to a look of intelligence and of independence, combined with the wrinkling and weathering of age, give an appearance which is not that of a child or of a cretin, and is still less like that of an ordinary adult. That beginning at a later period of life lacks some of these external features, but there is something strange, the size, proportion and facial characteristics of a boy or girl are combined with the carriage and manner of an older person. The condition of the skin showing age changes is especially notable. Such individuals undergo senile changes quite as early, if not earlier than those who are of normal development. There seems to be a form of the disease in which the skeleton appears to ossify at the time of puberty, and the sexual system go on to full development, but it is not common. Senilism is treated under much the same heads; there is premature development and rapid decay. He suggests the name *progeria*. This also has an abrupt onset and absence of appreciable cause and retained intelligence. Apparently only two cases have heretofore been reported, one of which is given here. In this the changes found on postmortem were atrophy of certain of the connective tissues, especially fat, with those of the bone which were laid down in membrane, as the skull, the periosteal bone of the shafts of the long bones and the lower jaw and clavicles, and certain epithelial structures like the skin, hair, nipples, etc., and also to a less degree, wasting and want of development of the muscles. On the other hand, there was a relative hypertrophy, or good development of cartilaginous structures, brain and nervous system. The liver was relatively large. In conclusion he refers to a case published by Drs. A. S. and J. B. Charcot of a cutaneous affection in which the skin changes were those of old age, thus differing from the ones he here describes.

21. **Myopia.**—On the basis of his observations Widmark offers the following thesis: "If by any cause the sight of the one eye is weakened in early childhood, myopia is developed exclusively or principally on the other (strong) eye, whether

the first-named takes part in fixation or passes on to convergent or divergent strabismus. If one of the eyes is lost a typical myopia may be developed in the remaining eye. Convergence equally with accommodation is, therefore, not one of the most important factors in the origin of myopia, for the myopia can arise independently of all convergence. The chief cause of myopia is "seeing" in a limited sense; the perception in the yellow spot and the processes connected therewith at the posterior pole of the eye. What these processes may be is not easily decided. But it seems to me not impossible that the effort of discerning the objects quickly following on each other—as, for instance, the letters in writing or reading—might lead to the hyperemia at the bottom of the eye, which some theories assume as a predisposing cause of the myopic changes at the posterior pole of the eye. Accumulated products of fatigue may also have a deleterious influence on the membranes. Hyperemia on its side may lead to softening of the tissues, which yield to the intraocular pressure. In more advanced cases the hyperemia and the products of fatigue may lead to more serious changes of an inflammatory or atrophic character." He does not deny all importance of convergence, but he is careful in his practice to facilitate the convergence by means of corrective glasses, especially in cases of muscle inefficiency.

28. **Cardiac Pain.**—In his first lecture Morison describes the anatomy and physiology of the heart and its innervation and circulation, and calls attention to the special pathologic changes which have to do with the production of angina pectoris. The atheromatous change in the coronaries is a very striking and important phenomenon in many of these cases, and he also notes a case of aneurism found in one of these vessels. He thinks that thrombosis as a cause is merely a hypothesis drawn from analogy with other parts of the body. He differs from Allbutt's opinion that all clinical cases of angina pectoris owe their origin to extracardiac causes, though admitting aortic disease may have its effect.

30. **Tuberculosis.**—Dean and Todd have experimented by passing tubercle bacilli of human origin through various animals, the pig, cat, rabbits and rats, injecting them in others and testing their virulence. In calves the effect seemed to be comparatively negative. Only local and gland lesions were found in some cases, in others none at all. The injection of pigs with matter obtained from human tuberculous subjects and the feeding of them with the same produced general fatal tuberculosis. The experiments seem to show that the human tubercle bacillus is not markedly exalted in its virulence for the calf by a single passage through the pig, cat or rabbit; still they show that it is not absolutely innocuous, as the control animal injected directly with sputum contracted an extensive glandular tuberculosis. This might seem to indicate that the passage through other animals produced a diminution of virulence, but it must be remembered that in the one case the associated organisms had been eliminated by passage, while in the other they played an important rôle by aiding the attack of tubercle bacilli. The experiments, however, indicate that pigs can be generally infected as result of inoculation with human tubercle bacilli.

34. **Test Alimentary Chloruria in Nephritis.**—Claude and Mauté have been making a special study of the test elimination of salt in the urine. The patients on a strict milk diet for at least four days, ingest 10 gm. of sodium chlorid dissolved in 125 gm. water, in three doses during the day. They refer to a case reported by Bujniewicz last year of traumatic injury of one kidney. All the urine from the fragment left was voided through a fistula, while that from the other kidney collected isolated in the bladder. The urine from the injured kidney showed an abnormally low proportion of sodium chlorid. The organ had to be resected later and the glomeruli were found sound while the convoluted and the straight tubules were profoundly altered. The sodium chlorid must have been absorbed by osmosis without any secretion on the part of the epithelial cells. Claude found that the response varied with the type of nephritis. In the parenchymatous form, when well or passably tolerated, the patients respond the same as normal subjects. When less perfectly tolerated the course of the

affection can be supervised and symptoms warded off by daily cryoscopic examination of the urine. In sclerous nephritis, on the other hand, the elimination of sodium chlorid differs completely from the normal type. After ingestion of the above amount it does not appear in the urine until the first or second day after the first dose, and the maximum may not occur until after complete cessation of the salt. The chloruria does not cease on suspension as in normal conditions, but continues for several days afterward. In advanced stages of nephritis ingestion of salt is not followed by any chloruria.

35. Cytodiagnosis of Tuberculous Pleurisy.—Barjon made cytologic examination of 43 cases of tuberculous pleurisy and is impressed with the great value of this method of differentiating the affection. The technic is simple, and although the findings in case of effusions in the joints and peritoneum and in the cerebrospinal fluid are not very reliable, yet in case of pleuritic effusions they seem to be constant. According to the experience accumulating on every hand cytodiagnosis is a rapid and an infallible means of differentiating tuberculous pleurisy. The proportion of lymphocytes ranges from 65 to 98 per cent., increasing as the affection continues. Defibrination reduces the number of polynuclear cells. Endothelial cells were found in two-fifths of the cases. The examination should be repeated several times on account of the variability of the formulæ in the earliest stages. The proportion of polynuclears is larger when there are pulmonary lesions.

37. Accidents Following Burial Under Snow.—Ferrier summarizes the reports of the surgeons connected with two companies of troops who were buried under avalanches in the Alps at separate times. The symptoms were those of acute asphyxia and loss of consciousness. The coldness of the snow evidently depressed the vital processes as in a hibernating animal. The respiratory passages also remained permeable and the snow always contains more or less air imprisoned in it. Owing to these facts the men who had been buried were restored on application of artificial respiration, rhythmic tractions of the tongue and peripheral stimulation to combat the asphyxia and syncope. To restore the central warmth the body was rubbed vigorously at first with snow, then with cold water, then gradually warming the water. These measures applied with perseverance and energy proved successful even in case of men who had been apparently dead for hours, and who presented unmistakable evidences of freezing of the tissues (the limbs partially stiff, the cellular tissue hard in the exposed regions). They were rubbed through their clothing out of doors. The warming must be done very gradually, and no hot fluids given to drink warmer than tepid, as blisters like those from a burn develop in the mouth if hot beverages are taken. The patient should not be allowed to sleep after he is resuscitated until all danger of syncope has passed. The asphyxia was just as acute after twelve minutes under six feet of snow as after two and one-half hours in the second accident, and the unconsciousness was as complete, but resuscitation was possible in both cases by these measures.

39. Early Sign of Rheumatism.—Achalmé points out that the early differentiation of acute articular rheumatism and institution of salicylic medication is of inestimable advantage to the patient. He has noticed in the clinic and confirmed the fact by experimental research that three or four days before the appearance of the phenomena in the joints the pathogenic agent of the infection invades the myocardium and the first symptoms of the infection are revealed at this point in arrhythmia. In a typical instance the pulse was only 56 and very irregular. The heart beat was vigorous, almost exaggerated, and the heart sounds corresponded to the disturbance, while its rhythm was much altered. The contractions were irregular, grouped in twos, threes or fours of uneven force and transmitted to the radial pulse with the same characteristics. There were no subjective symptoms on the part of the heart; but the patient sweated profusely and complained of a coated tongue, restless sleep and slight headache. Five days later the pains in the joints cleared up the diagnosis. This arrhythmia only lasted a few days, probably subsiding as the heart became accustomed to the infection. He has observed it

likewise in cases of relapse or recurrence of the infection and recommends it as a valuable sign of impending acute articular rheumatism.

45. Eruption of Mont Pelee.—Kermorgant reports that the lesions presented by the patients attended by the army surgeons after the August eruption of Mont Pelée, as well as the aspect of the cadavers, suggested the action of electricity. Several describe the view of the cloud that poured down from the mountain as sown with lightning and balls of fire, and Dr. Lidin reports that the air was strongly odorous of ozone. The clothing was intact and the burns seemed to be elective. A mother, for instance, was only slightly burned on the ear, while the babe in her arms was charred. Some of the deaths must have been due to asphyxiating gases as no traces of burns were found on many cadavers among those exhibiting burns. At the autopsies the internal organs were found much congested. The burns of the first and second degree, even the most extensive, all healed by the fifteenth to the twentieth day. All burns were cleansed from volcanic ash and dressed with a saturated solution of picric acid.

47. Heart Suture.—Two years ago Terrier was able to collect 11 cases in which the heart had been sutured, and mentioned at the time that the surgeons had operated by ten different methods. In this present communication, which was one of the addresses at the French Congress of Surgery in October, he has been able to find a total of 51 interventions on the heart. He states that he has tried on the cadaver all the various procedures that have been employed in suturing the heart, in addition to his clinical experience, and his conclusion is in favor of an outward opening flap. The incision occupies half of the second interspace, then is carried almost perpendicularly along the left margin of the sternum and extends downward and outward in the sixth interspace past its center. The costal cartilages are divided close to the sternum. The left hand is then inserted between the ribs and the pleura, inside a compress, and the pleura is detached with the fingers working through the compress. The latter is left as the hand is withdrawn to protect the pleura. It is unnecessary to cut the ribs as the flap is turned back; it is best to break each in turn to make the hinge. There need be no fear of injuring the detached pleura protected by the compress. Double ligature of the mammary artery is not always necessary, but is a wise precaution in all cases. The pleura is then turned back over the flap and compress, held by two forceps. It is unnecessary to detach the pleura from the triangular muscle. The pericardium is incised in a T to explore the auricles and the same T incision, reversed, is the most effective for exploring the rear aspect of the heart. The first and second fingers of the left hand can be introduced under the heart inside the pericardium, and bring it up into view. A wound in the rear can be explored by pivoting the heart on its long axis, holding it by the threads of the suture in the front. This method of procedure allows free access to all the heart except the right auricle. If this must be reached it may be necessary to resect a portion of the sternum. The pleura can be drained through the lower outer angle of the wound and the pericardium at the inner angle. Terrier does not claim that this method of procedure is applicable to all cases, but that it fits the majority and should be considered first. In case the intervention must be from the right side, he recommends a similar outward opening flap. Ten large cuts illustrate the various steps of the operation.

48. Thyroid Insufficiency and Eclampsia.—In this communication from the maternity at Nancy, the case is described of a woman with myxedema who passed through a pregnancy without symptoms, but during parturition eclampsia developed, without appreciable albuminuria. Lange and others have pointed out the sympathy between the thyroid gland and the genital functions evinced by the frequent hypertrophy of the thyroid in the fifth to sixth month of pregnancy and the subsidence of the hypertrophy under cautious thyroid treatment. Heile has also recently published a case of convulsions in a pregnant woman who had previously undergone partial thyroidectomy. From these and other clinical and experimental facts observed the conclusion is evident that certain cases of

eclampsia are due to functional insufficiency of the thyroid apparatus. Thyroid insufficiency induces chronic troubles, disturbances in nutrition, myxedema, while insufficiency of the parathyroid glands causes acute troubles, convulsions. The acute disturbances in cases of thyroidectomy are probably due to the ablation of the parathyroids. Although the thyroids and parathyroids are different organs, yet they are associated in their functions in all probability. When the thyroid gland does not become hypertrophied by the sixth month of pregnancy, the woman should be supervised in view of possible eclampsia. When the latter develops in a pregnant or parturient woman, especially if the thyroid gland is not hypertrophied, and if there is no albuminuria, it is possible that thyroid medication might prove beneficial. It has been tried by Lange in normal pregnancies without inconveniences, and Nicholson reports encouraging results from it in one case. In some of the experiments the thyroid insufficiency induced albuminuria in the animals. Consequently albuminuria is not inevitably a contraindication to thyroid medication.

49. Production of HCl.—Kornemann gives a series of tables and curves showing the absolute and proportional amounts of hydrochloric acid after a test breakfast, as determined at ten-minute intervals for three to six hours. Incidentally he was able to estimate the motor function at the same time. Half of the test meal had vanished from the stomach by the end of thirty minutes and only a quarter was left by the end of the hour. The absolute amount of hydrochloric acid reaches its maximum in twenty minutes after a test breakfast, remains at this point for twenty more, and then gradually declines. After a test dinner the maximum is reached in 120 minutes. He appeals to others to control these tests and thus establish a definite standard for normal conditions.

51. Pathogenesis of Gastric Ulcer.—Dalla Vedova's further experience has confirmed his previous conclusions and establishes that irritation of the celiac plexus or of the splanchnici in animals is liable to induce necrotic, hemorrhagic or ulcerative alterations in part of the stomach wall. They bear a close resemblance to the characteristic aspect and histology of gastric ulcer in man. (See also editorial in *THE JOURNAL* of Nov. 23, 1901, p. 1392.)

53. Power of Stomach to Digest Albumin.—Schorlemmer reports extensive research in this line undertaken at Boas' clinic. The results demonstrate the superiority of Mett's method for quantitative estimation of the pepsin. This ferment resists all injurious influences to the very last, and its determination is an important indication for treatment of gastric affections. The absence or gradual decrease of this ferment is a sign of severe destructive processes in the stomach. All the details of repeated examination of the stomach contents in 233 subjects are given in tabulated form. The list includes 40 with normal stomachs, 18 with gastric neuroses, 12 with carcinoma and 23 with hyperacidity. No parallelism could be discovered between the secretion of hydrochloric acid and pepsin in the majority of cases, but the production of pepsin seems to be exaggerated in cases of hyperacidity. There seems to be also a certain connection between them in gastritis anacida. The rennet ferment and pepsin do not parallel each other, as a general rule, but the rennet ferment and hydrochloric acid diminish together in cases of gastritis anacida. The digesting process is promoted by shaking.

54. Palpation of Pylorus.—Reviewed in *THE JOURNAL* of May 17, 1902, p. 1336.

55. Diphtheria Contagion from Healthy Persons.—Cuno describes an epidemic of diphtheria in a hospital for children at Frankfurt. Numerous cases occurred in various wards and the epidemic persisted, notwithstanding the most vigorous disinfection and isolation of the affected children. Neisser was consulted, and suggested that all persons in contact with the children, including the physicians, should submit to a bacteriologic examination. When this was done one of the nurses who suffered from a chronic throat affection, but was otherwise healthy, was found to harbor virulent diphtheria bacilli in her throat. Looking back over her service it was discovered that

the outbreak of the epidemic in each ward corresponded with her having been assigned for duty to the ward in question.

56. Forensic Importance of the Meconium Plug.—Weil does not agree with those who believe that the absence of the meconium plug has a medicolegal significance, but he does admit that the presence of the plug is suggestive that the child survived birth and succumbed later.

57. Disinfection of Instruments with Soap Tincture.—Gerson corroborates his former assertions as to the efficacy of disinfection of instruments with tincture of soap, citing extensive bacteriologic tests in evidence. He wraps the blades in Bruns' cotton impregnated with tincture of soap. The cotton protects them from the air and the tincture is an efficient disinfectant. The instruments are then ready for use at any moment. After using them he rubs them clean with cotton moistened with the same tincture, then wraps them in a fresh piece and lays them aside. No boiling nor steaming is required and the instruments are not harmed by the process. He recommends this method especially for military and other practice where steam disinfecting appliances are not available. He has found that instruments infected with pus, etc., and not even wiped off after having been used, proved perfectly sterile after a few days in the wet cotton wrapper. No colonies developed when they were rubbed on agar plates or soaked in bouillon.

58. Warning on Suprarenal Extracts.—Fürth is private docent of physiologic chemistry at Strassburg, and has already published communications warning against the intravenous use of suprarenal extract on account of its established toxicity by this route. He has recently observed a case of severe intoxication for several hours resulting from the injection into the urethra of a solution of suprarenal extract to arrest hemorrhage from an internal urethrotomy. The hemorrhage was checked at once, but attacks of syncope and twitching of the extremities recurred for several hours. He therefore warns against the use of the extract wherever there is any possibility that it might get into an open vein. Animals have succumbed with nervous, circulatory and respiratory symptoms after subcutaneous administration of suprarenal extract. Blum induced diabetes with it. Fürth urges caution in its use, as it is too valuable a remedy to be allowed to fall into discredit by carelessness in its administration and consequent accidents.

59. Scarlet Fever Serum.—In this auto-abstract of a communication to the Carlsbad Naturforscher Congress Baginsky states that he has examined the pharyngeal secretions of scarlet fever patients, and the organs of scarlet fever cadavers or the cerebrospinal fluid—a total of 696 cases—and streptococci were found in all but 5. Attempts to treat scarlet fever with Marmorek's and other antistreptococcus serum proved negative. Aronson, however, obtained a prepared serum from horses injected with streptococci from scarlet fever subjects, and this serum was used in the treatment of 26 patients with scarlet fever. Two were moribund and a third died with septic symptoms in the third week. The others recovered; 16 with no complications, and 7 with more or less severe complications. The effect of the serum treatment was encouraging, but not so strikingly beneficial as is the case with serum treatment of diphtheria. Baginsky injected 20 c.c. at a time and repeated the injections twice to six times. Further tests are now in progress, and the results are proving more encouraging than those here reported.

60. Surgery of Chronic Nephritis.—An abstract of Rovsing's article was published in *THE JOURNAL* of March 22, p. 796, when it appeared in Danish. See also editorial in *THE JOURNAL*, November 15, p. 1257.

61. Value of Bacteriology in Blood Poisoning.—Canon states that it is now a routine practice at the Moabit Hospital at Berlin to draw 2 to 5 c.c. of blood from the median vein and sow it on agar plates or glasses or in bouillon or to inoculate animals with it, in every case of blood poisoning, progressive phlegmon or general sepsis. This bacteriologic examination of the blood is made as early as possible, and the number of colonies that develop is recorded. The further increase or decrease in the number of colonies

on repeated examination is a criterion of the course of the general infection. In cases of progressive phlegmon in which amputation seems advisable, the question is decided by the increasing or diminishing number of colonies derived from the blood. The patient and his family recognize the necessity for amputation when they can see for themselves the increasing intensity of the sepsis. Canon's experience includes 93 patients and 65 cadavers. Pyogenic cocci were found in the blood in all but 12 of the latter, and death had been due in these cases to some other cause than the sepsis. He has been impressed with the fact that the finding of staphylococci is less important than when streptococci are encountered, especially when the staphylococci are an osteomyelitis. If anaërobic bacteria are found in the local process, they should be cultivated on suitable media as well as the aerobics.

65. True Cysts of the Liver.—Hofmann adds another to the 17 cases of true cysts of the liver which he has collected from the literature. Of the 15 in which the sex was mentioned, 4 of the patients were men and 11 women, including two girls of 11 and 14. All recovered after operation except 6.

66. Trephining for Headache.—Siegel operated on a patient on account of the solitary symptom of headache, and has found 11 similar interventions on record. All had a history of preceding trauma and all were permanently cured by the intervention. In each case there was some visible alteration of the skull at the site of the headache. The bone flaps healed perfectly in place.

68. Nature of Circulatory Disturbances in Acute Infections.—Pässler's latest researches confirm his previous conclusions that the disturbances in the circulation noted at the height of acute infectious diseases are due to paralysis of the vasomotors. The heart does not participate in their production at first. The toxins of diphtheria, however, have a certain action on the heart, altering the rhythm and rendering it less resistant. Nothing of the kind is observed in pneumococcus infection.

72. Uterine Insufficiency.—Atony of the uterus during and after childbirth was described thousands of years ago, but no one, Theilhaber states, has ever called attention to the insufficiency of the uterus which exists outside of the puerperal state. It is the same in kind as the former, and differs only in degree. He describes six various types of insufficiency, hypoplasia or degeneration of the musculature, myofibrosis, collateral hyperemia originating in the adnexa, uterus myomatous, and subinvolution. The consequences of this insufficiency are menorrhagia, metrorrhagia, hyperplasia of the parenchyma or hypersecretion. In all forms of insufficiency of the uterus there is a tendency to prolonged hemorrhages. The hemorrhage may last for weeks, or even months, without any appreciable anomaly in the mucosa. In treatment we have means to induce contractions of the uterus, to diminish the supply of blood to the parts, to reduce the blood pressure or to reduce the hyperplasia of the organ. In certain chlorotic subjects the menorrhagia diminishes after the administration of iron, which seems to contribute toward a new formation of the musculature. In the insufficiency due to troubles in the adnexa, or a myoma, removal of the cause may put an end to the menorrhagia. Hypersecretion may sometimes be controlled by stimulating the uterus to contract. This has long been known by empirical observation, but the reason for it has never been explained before, he remarks. He has found flushing the vagina with hot water a useful measure for this purpose. It has a mechanical action besides the stimulation from the heat. In rebellious cases he commences with water at a temperature of about 57 F. and follows this with an injection at 122 F. Ergot is peculiarly beneficial in case of a myomatous uterus. He recommends sitz baths to reduce local hyperemia, with water not over 77 F. Hydrastis canadensis is a valuable adjuvant, as it has a vasoconstricting action on the vessels in the lower abdomen. It is indicated when ergot fails or when the musculature of the uterus is so degenerated that no aid can be anticipated from ergot. Stypticin has a more general action on the blood pressure. Hyperemia of the uterus may also be controlled by

scarification of the organ or by introducing a tampon impregnated with glycerin. Reduction of the blood pressure in general has also a beneficial effect in cases of metrorrhagia and hypersecretion. This can be accomplished by hydrotherapy and dieting. A course at a watering place may prove beneficial if the patient can resist the temptation to overeat.

73. Malaria.—Gutiérrez has been successful in curing certain old and inveterate cases of malaria by injecting quinin directly into the spleen. Before the injection no young forms of the parasite could be found in the blood, but afterward they were numerous. The effect of the injection was always to precipitate an acute malarial attack, even in old chronic cases long free from such. He assumes that the forms of the parasite encountered in chronic cases and which are refractory to quinin, are stimulated to segmentation by the injection into the spleen, where they are ensconced. The recurring malarial attack coincides with the development of the younger generation, either from the mechanical effect of their eruption from the spleen or from the toxins generated by them.

75. Cold Packs in Pneumonia.—Escomel describes nine severe cases of pneumonia treated by the usual medical measures supplemented by two cold packs a day. Improvement was marked after the first application of the cold, the effect of which on the emunctories, temperature, etc., was promptly beneficial.

New Patents.

- Patents of interest to physicians, etc., October 21 and 28:
- 711697. Machine for testing lungs. Emma Donna, Chicago.
 - 711509. Thermometer attachment for fountain syringes. Ferdinand King, New York City.
 - 711910. Making sodium cyanid. Fritz Roessler, Frankfurt-on-the-Main, Germany.
 - 711605. Apparatus for treatment of diseases. Wm. T. Wells, Columbus, Ohio.
 - 712177. Apparatus for distributing odors. Charles T. Bradshaw, Philadelphia.
 - 712274. Making milk extracts. Otto Eberhard, Ludwigslust, Germany.
 - 712292. Dispensing apparatus for soda water. Charles A. Geddes, Philadelphia.
 - 712375. Human treatment apparatus. Isaac J. Hartford, Bloomington, Ill.
 - 712304. Respirator. Maurice Jacobs, New York City, and A. P. Black, Brooklyn.
 - 712321. Pumigator. Thomas H. McDonald, Elk Grove, Cal.
 - 712436. Therapeutic bath. Anton Pfister-Schmidhauser, St. Gall, Switzerland.
 - 712213. Atomizer. Albert H. Tatum, New York City.
 - 712225. Obtaining calcium sulphate and by-products. Herbert H. Wing, New Brighton, N. Y.
 - 712226. Obtaining alum. Herbert H. Wing, New Brighton, N. Y.
 - 712447. Magnetic medicine holder. Leonidas G. Woolley, Kenton, Ohio.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

INTERNATIONAL CLINICS. A Quarterly of Illustrated Lectures and Especially Prepared Articles on Medicine, Neurology, Surgery, Therapeutics, Obstetrics, Pediatrics, Pathology, Dermatology, Diseases of the Eye, Ear, Nose and Throat, and Other Topics of Interest to Students and Practitioners, by Leading Members of the Medical Profession Throughout the World. Edited by Henry W. Cattell, A.M., M.D., Philadelphia, U. S. A., with the Collaboration of John B. Murphy, M.D., Chicago; Alexander D. Blackader, M.D., Montreal; H. C. Wood, M.D., Philadelphia; T. M. Rotch, M.D., Boston; E. Landolt, M.D., Paris; Thomas G. Morton, M.D., Philadelphia; James J. Walsh, M.D., New York; J. W. Ballantyne, M.D., Edinburgh, and John Harold, M.D., London, with Regular Correspondents in Montreal, London, Paris, Leipzig, and Vienna. Cloth. Pp. 306. Price, \$2.00. Volume III. Series Twelfth. Philadelphia and London: J. B. Lippincott Company.

DICTIONARY OF PHYSIOLOGY AND PSYCHOLOGY, including Many of the Principal Conceptions of Ethics, Logic, Esthetics, Philosophy of Religion, Mental Pathology, Anthropology, Biology, Neurology, Physiology, Economics, Political and Social Philosophy, Philology, Physical Science and Education, and Giving a Terminology in English, French, German and Italian. Written by Many Hands and Edited by James Mark Baldwin, Ph.D. (Princeton), Hon. D.Sc. (Oxon.), Hon. LL.D. (Glasgow), Stuart Professor in Princeton University. With the Coöperation and Assistance of an International Board of Consulting Editors. In Three Volumes, with Illustrations and Extensive Bibliographies. Vol. II. Cloth. Pp. 892. Price, \$5.00. New York and London: Macmillan & Co., Ltd. 1902.

THE PRACTICAL MEDICINE SERIES OF YEAR-BOOKS, comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Issued Monthly. Under the General Editorial Charge of Gustavus P.

Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Volume I. General Medicine. Edited by Frank Billings, M.S., M.D., Head of the Medical Department and Dean of the Faculty of Rush Medical College, Chicago, and J. H. Salisbury, M.D., Professor of Medicine, Chicago Clinical School. October, 1902. Cloth. Pp. 358. Price, \$1.50. Chicago: The Year-Book Publishers.

A HANDBOOK OF MATERIA MEDICA, PHARMACY AND THERAPEUTICS, Including the Physiological Action of Drugs, the Special Therapeutics of Disease, Official and Practical Pharmacy, and Minute Directions for Prescription Writing. By Samuel O. L. Potter, A.M., M.D., M.R.C.P. Lond., Formerly Professor of the Principles and Practice of Medicine in the Cooper Medical College of San Francisco. Ninth Edition, revised and Enlarged. Cloth. Pp. 951. Price, \$5.00. Philadelphia: P. Blakiston's Son & Co. 1902.

THE PRACTICE OF SURGERY. A Treatise on Surgery for the Use of Practitioners and Students. By Henry R. Wharton, M.D., Clinical Professor of Surgery, Woman's Medical College of Pennsylvania, and B. Farquhar Curtis, M.D., Professor of Clinical Surgery and Adjunct Professor of the Principles of Surgery in the University and Bellevue Medical College of New York. Profusely Illustrated. Third Edition. Cloth. Pp. 1241. Price, \$6.50. Philadelphia and London: J. B. Lippincott Co. 1902.

DISEASES OF THE SKIN. A Manual for Students and Practitioners. By Joseph Grindon, Ph.B., M.D., Professor of Clinical Dermatology and Syphilis, Washington University. Series Edited by Bern B. Gallaudet, M.D., Demonstrator of Anatomy and Instructor in Surgery, College of Physicians and Surgeons. Illustrated with 39 Engravings. Cloth. Pp. 377. Price, \$2.00. Philadelphia and New York: Lea Brothers & Co.

A TREATISE ON MASSAGE. Its History, Mode of Application and Effects, Indications and Contraindications. By Douglas Graham, M.D., of Boston, Mass., Member of the American Association for the Advancement of Science. Third Edition, Revised, Enlarged and Illustrated. Cloth. Pp. 462. Price, \$4.00. Philadelphia and London: J. B. Lippincott Co. 1902.

THE SCIENCE AND ART OF PRESCRIBING. E. H. Colbeck, B.A., M.D. (Cantab.), M.R.C.P., (Lond.), D.P.H. (Cantab.), Physician to Out-Patients at the City of London Hospital, and Arnold Chaplin, B.A., M.D. (Cantab.), M.R.C.P. (Lond.), Physician to Out-Patients at the City of London Hospital. Cloth. Pp. 183. Price, \$0.57. London: Henry Kimpton. 1902.

A PLAN FOR THE STUDY OF MAN, with Reference to Bills to Establish a Laboratory for the Study of the Criminal, Pauper and Defective Classes, with a Bibliography of Child Study. By Arthur MacDonald, Specialist in the United States Bureau of Education, Washington, D. C. Paper. Pp. 166. Washington: Government Printing Office. 1902.

ANLEITUNG DIAGNOSE UND THERAPIE DER KEHLKOPF, NASEN UND OHRENKRANKHEITEN. Vorlesungen gehalten in Fortbildungscursen für praktische Aerzte von Dr. Richard Kayser, in Breslau. Zweite vermehrte und verbesserte Auflage. Mit 130 Abbildungen. Paper. Pp. 178. Berlin: S. Karger. 1903.

A TEXT-BOOK OF THE SCIENCE AND ART OF OBSTETRICS. By Henry J. Garrigues, A.M., M.D., Consulting Obstetric Surgeon to the New York Maternity Hospital. With 504 Illustrations. Cloth. Pp. 844. Price, \$5.00. Philadelphia and London: J. B. Lippincott Co. 1902.

TASCHENBUCH DER MASSAGE. Für Studierende und Aerzte. Von Dr. Frich Ekgren an der III medicinischen Universitätsklinik zu Berlin. Mit einem Vorwort von Geh. Med.-Rath Prof. Dr. H. Senator. Mit 11 Abbildungen. Cloth. Pp. 90. Berlin: S. Karger. 1903.

THE BLOOD: HOW TO EXAMINE AND DIAGNOSE ITS DISEASES. By Alfred C. Coles, M.D., B.Sc., of Public Health, Edinburgh. Second Edition. With Six Colored Plates. Cloth. Pp. 286. Price, \$3.67 net. Philadelphia: P. Blakiston's Son & Co. 1902.

SEVENTY-EIGHTH REPORT OF THE ROYAL SOCIETY FOR THE PREVENTION OF CRUELTY TO ANIMALS. Paper. Pp. 128. Price 1s. to Non-Members; by Post 1s. 3d.; by Continental Post, 1s. 4d. London: Secretary, John Colam.

REPORT OF THE SURGEON-GENERAL OF THE ARMY to the Secretary of War for the Fiscal Year Ending June 30, 1902. Paper. Pp. 185. Washington: Government Printing Office. 1902.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. Army, directed by orders from the Adjutant-General's Office, Washington, D. C., from Nov. 1 to 7, 1902:

Austin, R. E., contract surgeon, U. S. A., is granted leave of absence for two months, to take effect Nov. 20, 1902.
Carroll, James, first lieutenant and asst.-surgeon, U. S. A., will report in person to the Surgeon-General of the Army for assignment to duty as assistant curator of the Army Medical Museum.
DeWitt, Wallace, first lieutenant and asst.-surgeon, U. S. A., will report to the president of the faculty of the Army Medical School for the course of instruction prescribed by paragraphs 452 and 453, Army Regulations.
Edger, Benj. J., first lieutenant and asst.-surgeon, U. S. A., will report in person to the commanding general, Department of California, for temporary duty at the U. S. General Hospital at San Francisco.
Grubbs, Robert B., first lieutenant and asst.-surgeon, U. S. A., will report to the commanding general, Department of California, for duty at the U. S. General Hospital, San Francisco.
Minor, John F., captain and asst.-surgeon, U. S. V., is honorably discharged, to take effect Dec. 10, 1902, his services being no longer required.
Perley, Harry O., major and surgeon, U. S. A., is granted leave of absence for ten days.
Porter, Ralph S., major and surgeon, U. S. V., is honorably discharged, to take effect Nov. 12, 1902, his services being no longer required.

Price, Richard J., contract surgeon, U. S. A., will proceed to Ft. Bayard, N. M., and report to the commanding officer, U. S. General Hospital, for treatment.

The following named officers are honorably discharged, to take effect Dec. 9, 1902, their services being no longer required:
Major Thomas B. Anderson, surgeon, U. S. V.
Major Robert P. Robins, surgeon, U. S. V.
Major Charles H. Andrews, surgeon, U. S. V.
Major Frank H. Titus, surgeon, U. S. V.
Captain George W. Daywalt, asst.-surgeon, U. S. V.
Captain James K. Stockard, asst.-surgeon, U. S. V.
Captain Clarence H. Long, asst.-surgeon, U. S. V.
Captain George K. Sims, asst.-surgeon, U. S. V.
Captain William Aldin, asst.-surgeon, U. S. V.
Captain Willis Raynor, asst.-surgeon, U. S. V.
Sinks, Edward D., captain and asst.-surgeon, U. S. V., is honorably discharged, to take effect Nov. 15, 1902, his services being no longer required.

Marine-Hospital Changes.

Official list of the changes of station and duties of commission and non-commissioned officers of the Public Health and Marine Hospital Service for the seven days ended Nov. 6, 1902:

Assistant Surgeon-General J. H. White, granted leave of absence for 15 days from November 8.

Surgeon G. M. Magruder, granted leave of absence for 12 days from November 17.

P. A. Surgeon L. E. Cofer, relieved from temporary duty at Immigration Depot, New York.

Asst.-Surgeon W. A. Korn, granted leave of absence for 21 days from November 18.

Asst.-Surgeon J. S. Boggess, granted seven days' extension leave of absence from November 16.

A. A. Surgeon E. Alexander, granted two days' extension of leave of absence.

Medical Inspector Agnes Walker, granted leave of absence for 15 days from November 1.

Senior Pharmacist T. V. O'Gorman, relieved from duty at Louisville, Ky., and directed to proceed to New Orleans, and report the medical officer in command for duty and assignment to quarter

BOARD CONVENED.

Board convened at Port Townsend, Washington, Nov. 4, 1902 for the physical examination of such officers of the Revenue Cutter Service as may present themselves. Detail for the Board: P. A. Surgeon C. H. Gardner, chairman. Asst.-Surgeon M. H. Foster, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Nov. 8, 1902:

SMALLPOX—UNITED STATES.

California: San Francisco, Oct. 18-26, 1 case.
Colorado: Denver, Oct. 18-25, 1 case.
Illinois: Chicago, Oct. 25-Nov. 1, 2 cases.
Indiana: Indianapolis, Oct. 25-Nov. 1, 1 case.
Iowa: Ottumwa, Sept. 27-Nov. 1, 2 cases.
Kansas: Wichita, Oct. 24-Nov. 1, 1 case.
Kentucky: Covington, Oct. 18-Nov. 1, 22 cases; Lexington, Oct. 25-Nov. 1, 12 cases.
Maine: Biddeford, Oct. 25-Nov. 1, 1 case.
Massachusetts: Oct. 25-Nov. 1, Boston, 18 cases, 4 deaths; Cambridge, 1 case; Everett, 1 case.
Michigan: Oct. 25-Nov. 1, Detroit, 13 cases; Grand Rapids, 1 case.
New Hampshire: Nashua, Oct. 25-Nov. 1, 23 cases.
New York: Oct. 25-Nov. 1, Binghamton, 1 case; New York, 1 case; 1 death.
Ohio: Cincinnati, Oct. 24-31, 3 cases; Cleveland, Oct. 25-Nov. 1, 11 cases, 8 deaths; Dayton, Oct. 25-Nov. 1, 1 case; Youngstown, Oct. 18-Nov. 1, 1 case; 1 death.
Pennsylvania: Oct. 25-Nov. 1, Altoona, 4 cases; Erie, 3 cases; Johnstown, 6 cases; McKeesport, 3 cases, 1 death; Pittsburg, 18 cases, 6 deaths, 2 imported.
South Carolina: Charleston, Oct. 18-25, 2 cases.
Wisconsin: Milwaukee, Oct. 25-Nov. 1, 10 cases, 1 death.

SMALLPOX—FOREIGN.

Austria: Prague, Oct. 4-11, 8 cases.
Belgium: Oct. 11-18, Antwerp, 1 case; Ghent, 2 deaths.
Canada: Amherstburg, Oct. 18-Nov. 1, 3 cases; Quebec, Oct. 25-Nov. 1, 1 case.
Ecuador: Guayaquil, Oct. 12-19, 3 deaths.
France: Paris, Oct. 11-18, 1 death; Rhelms, Oct. 12-19, 1 death.
Great Britain: Liverpool, Oct. 11-25, 21 cases; London, Oct. 11-18, 4 cases.
India: Bombay, Sept. 30-Oct. 7, 1 death.
Russia: Moscow, Oct. 4-11, 3 cases, 1 death; Odessa, Oct. 11-18, 1 case; St. Petersburg, Oct. 4-18, 8 cases, 5 deaths.
Straits Settlements: Singapore, Sept. 6-20, 5 deaths.
Turkey: Constantinople, Oct. 12-19, 1 death.

YELLOW FEVER.

Columbia: Panama, Oct. 13-27, 12 cases, 1 death.
Ecuador: Guayaquil, Oct. 12-19, 1 death.

CHOLERA.

China: Hongkong, Sept. 20-Oct. 4, 5 cases, 4 deaths.
Egypt: Alexandria, Oct. 4-11, 72 cases, 71 deaths.
India: Bombay, Sept. 30-Oct. 7, 2 deaths; Madras, Sept. 20-Oct. 3, 3 cases, 3 deaths.
Japan: To Sept. 30, 11,228 cases, 6,302 deaths.
Korea: Seoul, Sept. 27, between 50 and 250 deaths daily.
Straits Settlements: Singapore, Sept. 6-20, 15 deaths.

PLAGUE.

India: Bombay, Sept. 30-Oct. 7, 112 deaths; Karachi, Sept. 28-Oct. 5, 27 cases, 22 deaths.
Japan: Yokohama, Sept. 27-Oct. 4, 1 death.

SYMMETRICAL GANGRENE (RAYNAUD'S) VERSUS ENDARTERITIS OBLITERANS.*

JAMES DUDLEY MORGAN, M.D.

PHYSICIAN GARFIELD HOSPITAL, ETC.

WASHINGTON, D. C.

SUMMARY.

1. Its Anatomic and Physiologic Consideration.
2. Relative Infrequency of Raynaud's Disease.
3. History of Two Remarkable Cases.
4. Etiology Relations of Each Disease to Other Morbid Conditions.
5. Progress and Termination of Each Disease.
6. Treatment.

INTRODUCTION.

Since the establishment of pathologic laboratories has come to be a necessity in all well-equipped hospitals, our knowledge of the etiology, progress and termination of disease has advanced *pari passu*. It may be easier and quicker to pass upon diseased processes without the labor and proper time spent in pathologic research, but true reasoning and systematic and correct classification of disease can only be obtained by comparison of the healthy and diseased areas.

There is, however, no question that in the subject under consideration in this paper, that the drawing of the line too sharply between similar diseases and the same diseases, has been the cause of much confusion and doubt, and too many phenomena have been looked upon as Raynaud's and too few as other diseases. It is openly held by many able clinicians that such a condition as true Raynaud's disease does not exist; others take the middle ground and speak of those cases as Raynaud's in which there are stages of syncope or asphyxia and gangrene, even though they show on examination a proliferation of the intima with partial or complete occlusion of the vessel. The question also arises, are there some cases in which this occlusion is due to a thrombus, which has become organized and is independent of the intima, but caused primarily by a disturbance in the circulation, dependent upon a vasomotor origin? The time necessary for the formation of a thrombus and its organization enters very sharply into the consideration of one of these cases presented. Zeigler thinks that a clot could hardly organize in less than a week or ten days; the rapidity in which the disease made its appearance in the case to be presented would seem to remove the theory of connective tissue growth as the incentive cause.

ANATOMIC AND PHYSIOLOGIC CONSIDERATION.

It seems to be the smaller blood vessels that are affected first in Raynaud's disease. The smaller the artery the more muscular is its middle coat, and so it is more capable of active changes in its caliber. Raynaud said the disease was due to a vicious innervation of the capillary system. The nerves, which are derived from the sympathetic system, penetrate the outer coat of the arteries to reach the muscular tissue of the medium, and these nerves, which are the dilators and constrictors of the blood supply, are controlled through their center in the spinal cord—the messages coming either from the periphery in the way of cold, heat, dampness, etc., or from the center by the toxicity of the blood or by way of higher mental and psychical impressions. It is a fact that uric acid in the blood is capable of causing vasomotor disturbance.

Many diseases may have the same appearance, yet arise from entirely different causes. The gangrene may be most extensive in both, and the ages of the patients may be about the same. Microscopically, the parts have little to differentiate them. The microscope may aid us as to the starting proliferation of the intima, showing changes in the muscular and thickening of the outer coat. Friedländer's disease (or obliterative arteritis (described in 1876) generally shows neuritis. In Raynaud's, even where there is gangrene, we do not necessarily find neuritis, and if it occurs it has been claimed by Dehio, Barlow, Collier and West that it is secondary to the gangrene. In short, as Monro says, Raynaud's gangrene may occur without neuritis, and apparently without either arterial disease or neuritis. It is explained that the nervous element in Raynaud's causes an abnormal excitability of the vasomotor centers in the spinal cord, producing a spasm of the vessels; this excitability of the vasomotor center may be brought about by stimulation of the centers by poisonings in the blood and reflexly by agents acting on the periphery.

RELATIVE INFREQUENCY OF RAYNAUD'S DISEASE.

There is no doubt that true Raynaud's disease is very much of a curiosity. It is beyond question a fact that many cases of symmetrical gangrene are tabulated as Raynaud's, when an examination of the arterial system would have shown hardened arteries with perhaps hypertrophied heart, accentuated diastolic aortic sound, or displaced apex beat. Further examination of the dead area in section, either macroscopically or microscopically, would reveal occluded vessels, both in and above the necrotic region. A continued paroxysmal contraction in the vessel may lead to thrombosis, but there should not be in true Raynaud's a proliferation of the cells of the intima, leading thereby to a slowing in the blood current, and a necessary following of thrombosis.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Richard Dewey and H. A. Tomlinson.

HISTORY OF TWO REMARKABLE CASES.

One of these two cases which I here report can very clearly be put down as endarteritis obliterans; the other has so many remarkable and analogous features to Raynaud's disease that its tabulation is even yet in much doubt.

CASE 1.—A Jew, aged 35, who had always enjoyed good health up to the age of 25.

Family History.—Father died when eighty of tuberculosis. Mother died during confinement.

Previous History.—Born in Poland. Was a healthy child. Made good recoveries from the usual diseases of childhood. Had malarial fever five months ago. Has always been healthy other than gangrene in right leg ten years ago. "The gangrene in the first instance came from frost bite." The history of specific disease could not be obtained, and only an exposure to extreme cold during severe army service in Europe, some ten years ago, could be found as a contributing cause to the extreme gangrene.

Present Illness.—First noticed trouble with left leg about four months ago. Went to hospital. The gangrene began in the toes first and gradually worked up. Contraction in the leg began about the same time as the gangrene.

Examination.—The radial arteries were found calcareous and nodular, especially the right. The heart sounds were feeble, but clear of murmurs. Examination of the fundus of the eye showed the vessels markedly narrowed. The urine was of low specific gravity (1006), but otherwise normal. Temperature ranged from 95 F. to 104.4.

Fig. 1.—Symmetrical gangrene.

Operation.—By Dr. Thompson. Left knee of thigh aseptically prepared. Incision beginning at upper end of lower third on outer side of thigh and extending down, making a long anterior flap. The periosteum was dissected back and the femur sawed through at the junction of the lower and middle thirds. The arteries were found to be extremely calcareous. The muscles were sewed together over the bone with catgut and the wound was closed with interrupted sutures of silkworm gut. The parts failed to heal properly after operation and patient died of asthenia, about two weeks afterward.

The second case was very remarkable from the extensive gangrene, which simultaneously attacked all four extremities, being preceded by previous good health and with only very short premonitory symptoms of tingling, numbness, heaviness and deadness of the extremities. A condensed history, with a photograph of the patient (Fig. 1) and photo-micrographs of sections (Figs. 2 and 3), together with drawings of the parts by H. C. Macatee, M.D. (Figs. 4, 5 and 6), and notes of the pathologist of Garfield Hospital, Dr. Nichols, are here presented. In addition, the notes of the ophthalmologist, Dr. W. K. Butler, who made several examinations of the fundus of the eye at different times is also added.

CASE 2.—*History.*—Maria Harris, colored, aged 35, married, born in South Carolina, laundress, entered Garfield Hospital, Washington, D. C., Nov. 19, 1901, in the service of Dr. J. D. Morgan.

Previous History.—Healthy child, had pertussis and measles in childhood; had rheumatism, principally in shoulders, for two weeks in January, 1901; otherwise enjoyed good health. Always worked hard. Married but no children, no miscarriages or abortions; no menstrual disorders. No history of ergotism, no specific history.

Present Sickness.—Latter part of October, 1901, about mid-day was taken with severe paroxysm of vomiting, and same day, hands and feet felt numb, and very soon following this (few days) tips of fingers commenced to turn dark and dark-greenish, and there was trouble in using them. Had difficulty in walking and found that tips of toes were black and cold; the process beginning at the tips of fingers and toes and working upward, the right hand more than the left. Patient suffered at times, but not greatly.

Examination.—On entrance to hospital, temperature 97.6 F. Anemic. No gastric or intestinal symptoms; bowels regular; appetite good. No respiratory symptoms. Systolic murmur at aortic orifice; heard at apex, but intensified upward toward the second intercostal space, right side. Arteries soft and compressible; no tension or hardness. Leucocytes vary from 6000 to 15,000 per cm. Nov. 26, 1901, leucocytes were 30,000. Urine: sp. gr. 1006 to 1010, otherwise negative. Both legs and right hand highly gangrenous (see Fig. 1); left hand had tips of three fingers black and shriveled; very marked odor; no lines of demarcation.

Fig. 2.—Anterior tibial. Magnification 35 diameters. Showing vessel filled with an organized granulation tissue. Little or no thickening of intima.

First Amputation.—Dec. 26, 1901, by Dr. Snyder. Parts all now thoroughly demarked, with healthy granulations. Patient's general condition very good. Removed right hand above wrist and left leg just below knee. Before amputation, temperature most of the time normal, except on two or three occasions it went to 101 F.; after first amputation between 100 to 101 for four or five days.

Second Amputation.—Jan. 16, 1902. Chloroform the anesthetic. Removed right leg below knee. Temperature after second amputation from 99 F. to 101 F. for one day. The three fingers of the left hand required no surgical treatment, but healed gradually and properly, with only the loss of the nails and thickened epidermis.

Results.—May 17, 1902. No return of disease, patient well. Appetite good, is cheerful, has gained flesh, no pain or fever.

Treatment.—Parts soaked daily for 10 minutes in 2 per cent. carbolic acid solution of temperature 110 F.; wrapped in absorbent cotton. Whiskey, strychnia, nitro-glycerin and nutritious diet given freely. Galvanism of parts q. a. d. Anode to spine and cathode to hand or leg (descending). No sedatives or narcotics used at any time.

Macroscopic Examination.—By Dr. Nichols, Dec. 27, 1901: The specimen consists of a leg completely gangrenous from

the middle down. The gangrenous portion is separated from healthy portion by a broad interval of demarcation, 1 to 2 cm., crossed only by tibia and fibula, and a few dead shreds. The stump, above the self-amputated soft tissues, presents a granulating surface. About 5 or 6 cm. of the tissues, above the line of demarcation, were removed in the amputation, and are available for examination. In cross-section, about 5 cm. above the line of separation, the anterior and posterior tibial arteries appear completely occluded by a white tissue. At lower level, 4 cm., these vessels appear similarly occluded, but the material is of a deep brown color, like a thrombus.

Microscopic Examination.—Cross section about 5 cm. above line of separation shows posterior tibial artery completely occluded, and anterior almost, by a growth of connective tissue, continuous with the tunica intima; although directly continuous with the tunica intima, it is different in character, and there does not appear any real thickening of the tunica intima; the new tissue has capillaries and small blood vessels. At 4 cm., same condition, except cells filled with brown pigments (broken down blood pigment). One of the tibial veins and few small arteries show distinct and marked thickening of tunica intima (obliterating endarteritis). Nerve trunks show no morbid changes.

Examination of Fundus of Eye.—Right eye: media clear, retinal arteries apparently normal size, veins apparently slightly enlarged. Left, nerve head not as clear as right, light streak on arteries, not well defined. Vessels appear normal, perhaps slightly smaller in caliber.

Fig. 3.—Posterior tibial. Magnification 25 diameters. Showing vessel filled with an organized granulation tissue. Little or no thickening of intima.

The notes of this case were sent to Professor Osler at Johns Hopkins, and also to Prof. Thomas K. Monro of Glasgow, who has written most extensively recently of Raynaud's disease. The letters of comment on the case are here presented:

BALTIMORE, Md., Feb. 19, 1902

Dear Dr. Morgan:—Thanks for your paper. What a remarkable case! It belongs to a group of very great interest, and cases are more common in children than in adults. Very much obliged indeed for the photograph. I have long been collecting these cases. You should report it

Sincerely yours,

W. OSLER

GLASGOW, SCOTLAND, March 20, 1902

Dear Dr. Morgan:—Thank you very much for the notes of the case of symmetrical gangrene, and for the excellent photo, which reached me in safety.

The case is one of a remarkable group with regard to which anatomic observations such as yours are particularly desirable. In this case, *disease of the arteries is clearly not the cause of the gangrene*; first, because the anatomic investigation appears to exclude it, and second, because the simultaneous and acute or sudden onset in all the limbs is quite inconsistent with such a theory. The history of a recent attack of rheumatism and

the presence of a cardiac murmur raise the question of embolism, but we can not suppose that this would occur simultaneously in all the limbs, while sparing the rest of the body. Neuritis is, of course, excluded by the anatomic investigation and by what we know of the symptoms of that disease.

Different views are held by different observers as to the nature of such cases as the present one, and I have briefly alluded to the subject in my monograph (pp. 208-9, 102, 106-7, 173). Prof. Osler ("Prin. and Pract. of Med.," 4th ed., p. 1138) and others admit them to the category of Raynaud's Disease, but to do this, we must make the expression "Raynaud's Disease" more comprehensive than is consistent with Raynaud's own theory of the affection. If an intense increase of vasoconstrictor activity exists in the limbs for a few hours, and then

Fig. 4.—Symmetrical gangrene. Second case

passes off permanently, leaving gangrene behind it, we can scarcely refer it to increased excitability of the vasomotor. It seems possible that some agent (toxic, reflex or otherwise), having itself only a transient influence or existence in the body, caused an intense but transitory stimulation of the vasoconstrictor center. It is indeed strange that such paroxysms should not recur. With kind regards, yours very truly,

10 Clairmont Gardens.

T. K. MONRO.

ETIOLOGY; RELATION OF EACH DISEASE TO OTHER MORBID CONDITIONS.

Both Raynaud's and endarteritis obliterans occur frequently in middle life. Cases of Raynaud's have been

reported as occurring as early as three months (W. W. Johnston), and are more frequent in females. Endarteritis obliterans has been reported as occurring as early as twenty-three, and is more frequent in males. The first symptoms in one of the writer's cases were at twenty-five, and were so severe and progressive that one limb was amputated for gangrene. The development of gangrene in the old rather excludes a diagnosis of Raynaud's or primary endarteritis obliterans. Raynaud found his cases so often in the young that he proposed calling it "juvenile gangrene." Senile gangrene is typically unilateral, and if symmetrical not *synchronously*. The structural change in the blood vessel leading to proliferation of the intima is not sufficient of itself, even in young adults, to make the case pathognomonic of syphilis. The history of syphilis in Raynaud is considered more of a coincidence, than causative agent.

Raynaud contended that one essential was necessary, the successive paroxysms of syncope, asphyxia, leading finally to gangrene; that the paroxysms were spasmodic and that there were frequent and recurrent contractions of the walls of the arterioles supplying the extremities attacked. It was noted that a considerable number occurred in the first ten years of life, then fell off and became numerous again at fifteen to thirty years. The evolution of the nervous system in the female and occupation in the male was put down by Monro as the distinctive cause.

Phlebitis leads to moist gangrene; it is seldom symmetrical, and the gangrene is generally fatal.

Among the other causes in Raynaud's disease, heredity is put down as responsible in 8 per cent.; exposure to cold is a predisposing cause, and so also is rheumatism (7 per cent.); malarial fever often seems also associated with the disease. Tuberculosis is found in 6 per cent. of cases. Leucocythemia is rarely noted, but nephritic trouble is associated in 17 per cent. of the cases.

There is little resemblance to peripheral neuritis. The symptoms of incoördination, tenderness of muscles and nerves, with paralyses, make the case clear. There is a large field of cases which has been referred to as acro-neuroses (Dana, 1885), under which Raynaud's disease may perhaps be indefinitely classed. Disturbances of the nervous system have been referred to as being the cause in 4 per cent. of the cases. G. S. Badger, M.D., in a recent article, says: "It has been noticed particularly in asylum cases, as a manifestation of hysteria, and as a complication occurring in the course of many organic nervous affections." A letter from the Government Hospital for the Insane, which has nearly 2500 inmates and the experience of Drs. Richardson and Stack, who have come in contact with over 10,000 asylum cases would seem to put Raynaud's disease as less frequent in asylum cases than any place else.

Fig. 5.—Symmetrical gangrene. Second case.

Among rare contributing causes of symmetrical gangrene Raynaud admits valvular defects and congenital narrowing of the aorta and of the systemic arteries. Diseases of the cardio-vascular system are found in fully 12 per cent. of cases, and aortic systolic murmur in 5 per cent. of the 12 per cent. of cardiac cases (Monro). Embolism is rarely symmetrical, and it would be remarkable indeed for emboli to lodge in all four extremities and do no damage elsewhere.

Glycosuria cases are not easily mistaken. The examination of the urine and the whole history and appearance of the parts characterize the diseases. Of the modifications of sensations, analgesia is the most common; although the sense of touch is blunted, still the appreciation between heat and cold is distinct. Warm applications were most grateful in the case of the writer, whereas cold seemed to cause suffering. There is a similarity between hemoglobinuria and Raynaud's disease, in that exposure to cold produces paroxysms; but in the one case the nerves and walls of the blood vessels suffer, in the other the blood and the blood-producing organs; in hemoglobinuria we often find albumin, hemoglobin, and even red corpuscles in the urine. Cases of erythromelalgia seldom lead to gangrene, and are aggravated by warmth and relieved by cold; the pain is generally present and the ulceration is confined to one extremity.

Fig. 6.—Symmetrical gangrene. Second case. No loss of fingers entirely well.

GOVERNMENT HOSPITAL FOR THE INSANE.

A. B. Richardson, M.D., Supt.

WASHINGTON, D. C., May 5, 1902.

Dear Doctor Morgan:—I inclose the data of the case of Raynaud's disease as furnished by Drs. Stack and Pulliam, who had the patient in charge. I am sorry I can add nothing to what is given, as this is the only case I have ever seen. You have, of course, the verbal assurance of Dr. Richardson that in a long experience he has not met with a case; and the case now under consideration is the only one seen during the long service of Dr. Stack in this institution. Hoping that I may have the pleasure of hearing your paper, I am, yours very sincerely,

I. W. BLACKBURN.

SYNOPSIS OF CASE OF RAYNAUD'S DISEASE IN WARDS OF DR. STACK.

"C. Mc., aged 66; married; occupation, laborer and soldier; nativity, Ireland. Previous history, addicted to excessive use of alcohol. He has had epilepsy for several years. Present attack: On February 2 patient complained of his feet paining him very much, and on examination I found that a number of blebs had formed on toes, soles of feet and instep of one foot; these blebs were opened and dressed antiseptically. February 3, examination revealed that the blebs had filled again, and the contained serum had undergone a certain amount of organization; following this the pain passed away and the toes became very black and the superficial structures sloughed off, leaving a pearly white base to ulcer. In a few days the toes became very

much inflamed and somewhat painful, but the pain lasted only a day. The toes remained in this condition for about one month, with but very little change. The ulcers healed gradually, and the inflammation subsided; the nails were cast off about one month after the onset. The patient's toes are now entirely healed and give him no trouble at all."

J. M. PULLIAM.

A case recorded by Dehio, and reported by Mouro, offers a striking proof that Raynaud's symmetrical gangrene can occur as an independent and typical disease in persons otherwise healthy: the patient was a woman, aged 31, and the disease followed a severe fright due to an assault at night by several men. There was extensive gangrene and the parts were amputated seven months after the onset. The vessels showed on examination a fibrous endarteritis and endophlebitis. The lumen in some vessels was completely obstructed by partially organized thrombi, but here, too, the fibrous thickening of the intima was distinct.

PROGRESS AND TERMINATION.

Raynaud's disease never causes death and seldom shortens life. Why it should cease is sometimes quite as mysterious as why it should begin. With the gangrene there is seldom any sepsis; the parts tend to demarcation, and it is better not to amputate; anyhow, always wait for healthy granulation. Arterial obstruction in typhoid, which leads to gangrene, is generally fatal. Senile gangrene affects by preference the lower extremities; it is progressive and serious. Other diseases associated with gangrene generally tend to fatal termination.

TREATMENT.

In Raynaud's and those strongly simulating it, the treatment has been given in the history of one of the cases. With regard to the other cases, the treatment is not so successful. A natural and easy trend in life is much better in those with arterial degeneration. The iodids and nitrites are of use. Among the baths, a course of Nauheim (which can be followed here or abroad) give best results. A scrupulous regulation of all the functions of the body, with the avoidance both of alcohol and of choking the system with improper and too much food, and a regular and systematic outdoor life and exercise, are the cardinal points. If gangrene should appear in endarteritis obliterans, the sooner you operate, the better the result.

A SIMPLE SINGLE-DISC EYE MIRROR.

THE WORKING OPHTHALMOSCOPE FOR THE EYE SPECIALIST AND GENERAL PRACTITIONER, AND HOW TO USE IT

HERMAN KNAPP, M.D.

NEW YORK CITY.

The many modifications of Helmholtz's eye mirror in the course of fifty years show that there was at first a tendency to simplification, to make the original instrument handier and more expeditious. Thus the small Liebreich's ophthalmoscope, a concave mirror with a clip behind the sight-hole for a few lenses, mainly destined to correct the physician's myopia, readily became very popular on account of its easy handling and the brilliancy of the fundus image, which never has been surpassed. The inconvenient clip was soon replaced by a disc revolving on the back surface of the mirror, putting a number of correcting lenses successively behind the sight-

hole. This has been the most important practical improvement of Helmholtz's instrument. Large demonstration ophthalmoscopes soon followed, from Ruete's instrument to Thorner's, the latter being a marvel in distinctness and brilliancy of the picture, which is free from reflexes and larger than the erect image. All those instruments are not for daily practice.

The advantages of determining objectively the optical condition of the eye led to the construction of the so-called refraction ophthalmoscopes. The new features which they introduced were the increase of correcting lenses, to be placed in one or several revolving discs, and the tilting of the mirror by Dr. Wadsworth of Boston, to obviate the disturbing astigmatic effect when the rays of light fall very obliquely on the correcting lenses. Applying those principles in diversified manner has produced a multitude of ophthalmoscopes, ingenious in design, complicated in construction, and more or less cumbersome, without surpassing, mostly falling behind, the distinctness and brilliancy of the small Liebreich (he constructed also a large demonstration ophthalmoscope), or the simple mirror with a sufficient number of lenses in a Rekoss disc. The latter is the working ophthalmoscope which I have constantly used in private and hospital practice, and I have not found any occasion to replace it by a better one these thirty years.

The concave glass mirror has a sight-hole of 3 mm. The rotating disc has one empty hole and 23 fitted with small lenses, from + 0.50D. to 12D., and from -0.50D. upto -20D. The rotating disc applies close to the edges of the sight-hole of the mirror, so that the walls formed by the sight-hole in the mirror and those of the rotating disc which holds the lenses are reduced to the smallest possible dimensions. This is important in order to let enough light through and avoid the unpleasant reflexes from the canal walls. If these walls are well blackened they cast no appreciable reflex on the eye. The blackening is easy, and even if the mirror is constantly used the blackening need not be repeated for many months. I do not usually put my mirror into its case, but carry it in the breast pocket of my coat, constantly taking it in and out. The lenses may gather a little dust, which is easily removed with a camel's hair brush or with a cotton-tipped probe every now and then. What soils the glasses and interferes with sight is fat from the fingers and similar sticky substances which prevent the regular refraction of the rays of light. The correcting lenses are, however, well protected in front by the mirror, be-

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, H. V. Wurdemann and J. A. Lippincott.

hind by a metal plate covering the rotating disc. Two convex lenses, one of 24D., the other of 12D., complete the ophthalmoscope.

The best light for ophthalmoscopy, so far as I know at this time, is an Argand gas burner, or a broad, round oil or kerosene lamp, because both are not too glaring and have the same kind of light which is reflected from the background of the eye, namely, yellowish-red. Electric and Welsbach light have not given me the same satisfaction. Habit plays a great part in this work, and any coming month may bring us a better light for our examinations than gas.

After having made a careful ocular inspection and a cursory functional examination (sight and visual field) of the eye, the patient is taken into a dark room and the anterior part of his eye is examined with oblique light. This is a very important examination, revealing minute abnormalities in cornea, anterior chamber, iris, lens and anterior part of the vitreous. After that you examine the patient's eye with the ophthalmoscope by transmitted light, either without or better with a convex lens behind the sight-hole, and see whether you get the normal (uniformly red) fundus reflex or whether it differs from it totally or in one or several parts of the pupil. This reveals abnormalities of the refractive media, cornea, lens and vitreous, always using a + lens behind the sight-hole of the mirror, so as to look with relaxed accommodation. For the emmetropic eye this is + 3D. or + 4D., for ametropic eyes their distance glass has to be added. For opacities in the anterior part of the eye a stronger lens is often very useful for distinguishing small objects, such as minute dots on the posterior surface of the cornea, or the fine dots and streaks in primary and secondary cataracts. Unless the eye is very myopic or very hyperopic you see nothing of the background.

The background can be examined in the inverted or in the erect image. I have been taught to begin with the inverted image, also using constantly a + lens of 3D. or 4D., so as to get into the habit of always looking with relaxed accommodation, which will give an enlarged image, almost the size of the erect. The patient stands or sits near the light, you throw the light into the pupil (previously dilated if too small), then you hold the +12D. lens 3" before the eye, so that the light passes through the lens and pupil to the retina and choroid, from where it is reflected on the same way into your eye, giving you an inverted image of the objects in the fundus. The technic of all this is best acquired from an instructor. By this method you receive a smaller image, but you overlook a much greater part of the background than with the direct method (erect image). You move your head from one side to the other and let the patient look about so that you obtain a perfect survey of the eye, and can, in most cases, make a satisfactory diagnosis of the condition of the background.

If there are parts which you do not see large enough, you have to examine the eye with the *direct method* (erect image). For that you turn the Rekoss disc in such a way as to have the empty hole behind the sight-hole, place the patient two feet before the light and look into his right eye with your right, into his left eye with your left, as close to his cornea as 13 mm. if possible. In this position the visual line of the patient, your own visual line, and the pencil of light passing from the lamp into your eye are sufficiently in the same direction to cause no distortion of the fundus-picture. This position, upon which Helmholtz dwells, allows you to dis-

pense with the tilted mirror. I have often made control examinations with a tilted and with a fixed mirror, and have arrived at the same result with regard to the optical condition and the shape of the objects in the background. If, as it is customary, the patient is placed sideways of the light, then the rays passing through strong lenses behind a fixed mirror cause sufficient distortion to vitiate the result of the examination. It is advisable for beginners, and also with narrow pupils or dull media, to have the pupil dilated, best with a drop or two of a 5 per cent. solution of euphthalmin, or with $\frac{1}{4}$ per cent. or $\frac{1}{2}$ per cent. solution of homatropin.

So much, gentlemen, I would ask your indulgence for a plea to use a simple ophthalmoscope. The complicated instruments mostly do not indemnify us for the loss of time required in their use. An excellent teacher (Robert Koch) advised me in the outfit of the microscope to have only three lenses, one with 30 to 50, another with 300 magnifying power, and a third an oil immersion of $\frac{1}{12}$; "the others are useless." With regard to the two methods of ophthalmoscopic examination, I frequently see young oculists who come to my clinic use first and only the direct method and pass an inordinate time in looking into the patient's eye without finding what I direct their attention to. When I ask them why they did not examine the patient in the indirect method, they answer that they had been taught the direct only, and had been told the indirect was superfluous. As this has also been expressed in some of our modern text-books, I should like to know whether this opinion is prevailing. I, from my experience, would regret if the method of examination in the inverted image were to be neglected, for I find it indispensable.

"A certain profession of dogmatism," says a great surgeon in an address to medical students, "is essential in the treatment of the sick. The sick man will allow of no hesitancy in the recognition of disease. He blindly demands that the appearance of knowledge shall be absolute, however shadowy and unsubstantial may be the bases of it." But is this good advice? It is, so far as the patient is concerned, usually true at the time of illness, but there are several other considerations which we believe make the advice to the physician the reverse of wise. In the first place there are the patient's relatives and friends. Even in hospital practice and in private practice among the poor it is not true that the physician succeeds in humbugging the friends by an assumed dogmatism without the reality of knowledge and conviction. Among intelligent laymen, far more frequently than is supposed, one will find that any such sham certainty is at once detected. Doctors make a great mistake when they think their deceits really deceive. Then there is the patient who recovers. When he is well the false diagnoses, the changes of dogmatic opinion and medicines, the blind alley of proved errors—these are thought over, and the doctor is scorned, not loved. This is, in fact, the origin of the famous saw concerning the wish of the devil to become a monk when he was sick, etc. Thirdly, comes the reaction on the dogmatist's character. One can not dishonestly assume knowledge, and skill, and prophecy without at last fooling himself, and he then enters upon a life of continually descending tactlessness in which the fraud becomes proportionately more evident to others as it becomes more unconscious to self. The profession suffers also, because to it is charged the sin of the tricky doctor. Slyness, assumed virtues and knowledge, cunning—these do, in fact, prevent true professional success. But the foolish sly ones will never find it out.—*American Medicine*.

No Ice-Cold Drinks in Berlin.—The municipal authorities of Berlin, with a fatherly solicitude for the stomachs of the burghers intrusted to their guidance, have issued a decree that no iced drinks shall be sold in any place of public refreshment in that city. The limit of frigidity allowed is 10 C., or 50 F.—*Medical Record*.

ASSOCIATED MOVEMENTS OF HEAD AND EYES.*

WILLIAM CAMPBELL POSEY, M.D.

Surgeon to the Wills Eye Hospital; Professor in Ophthalmology at the Polyclinic Hospital.
PHILADELPHIA.

In order that the body may properly perform its functions and all the organs act in harmony, a certain reciprocity must be maintained between the different parts. Nowhere is this reciprocity, this association of action, better observed than in the movements of the head and eyes. Upon account of the protected position of the eyes and the direction of the plane of the orbit in the human skull, the field of sight is restricted much more in man than in some of the lower animals where the eyes are much more mobile, and were it not for the increase in the range of the field of sight which the rotation of the head affords, man would be unable to perceive many side objects without change of position of the entire body. Not only does the head, however, by its movements, augment the range of the field of vision, but it also supplements the action of the extra-ocular muscles in the delicate task of maintaining proper visual axes. To properly perform this two-fold task the head is provided with numerous and intricately acting muscles, and it is only when we remember that there is scarcely a position assumed by either the eyes or head in which the action of both parts do not enter, that we realize how intimate the relationship between the extra-ocular and cervical muscles is; indeed, it might be added the musculature of the entire body as well, for it is usual for the muscles of the trunk to be implicated in a greater or less degree in all vicarious positions of the head.

It is not the intention of the writer to approach the subject of these associated and vicarious movements from an anatomic or a physiologic standpoint, but rather to record some clinical observations which he has recently had an opportunity of making on several subjects who presented such movements. To facilitate this study the movements of the head and eyes which may occur in association have been classified into four groups:

1. MOVEMENTS WHICH ARE PHYSIOLOGIC.

Under the class of physiologic movements are included the many and varied movements which the head makes through the medium of the neck muscles in supplementing and augmenting the action of the extra-ocular muscles. Such movements are often involuntary and are almost constant; and though their mechanism is complicated and intricate by reason of the close association in the cerebral innervation of both extra-ocular and cervical muscles, both sets are enabled to act in perfect unison.

2. ABNORMAL INDEPENDENT BUT SIMULTANEOUS MOVEMENTS.

Movements which are abnormal and though simultaneous and having the same pathologic origin are not related in the sense of being dependent on one another, constitute the second class. Under this is included the accidentally simultaneous occurrence of nystagmus and head tremor in certain diseases of the cerebrospinal system, as, for example, in disseminated sclerosis and in paralysis agitans. As is well known, nystagmus is one of the characteristic symptoms of disseminated sclerosis, while head tremor is a comparatively unusual manifestation; yet both the movements in the eyes and the tremor

in the head may occur in the same subject at the same time, without either being responsible for the other, the associated conditions being due to sclerotic foci in the vicinity of the nuclei of both sets of muscles. In paralysis agitans the head not infrequently presents conspicuous tremor in consequence of contractions in the superficial and deep cervical muscles, but the muscles of the eye are but rarely affected. Debove, however, has noted in rare cases a retardation in the movements of the eyes which, if the patient was reading, occasioned a characteristic pause at the end of each line, and Galozowski also has observed imperfect movements of both eyes and head in this disease.

3. COMPENSATORY MOVEMENTS.

The third class is a vicarious position of the head. Assumed to compensate for some imperfect action of one or more of the extra-ocular muscles. On account of the close physiologic association between the extra-ocular, the cervical and some of the trunk muscles, in the event of the failure of one of the eye muscles to properly perform its function, this latter may be assumed by some of the muscles of the other groups, but always at the expense of the proper head posture, for a deviation in one set of muscles can only be compensated for by a secondary deviation elsewhere. This act of compensation is well seen in paralysis of an eye muscle, where it is a known law that to avoid the diplopia and visual vertigo which such a palsy occasions, the head is turned in the direction of the affected muscle, thereby supplementing its action, so that for every variety of palsy there is a characteristic pose of the head. A similar deviation, though to a less extent, may be observed in cases of imbalance of the extra-ocular muscles which are latent, the so-called phorias.

An extremely interesting class of cases which the writer would include in this group, as an example of compensatory head movements, is the wry neck, which has been observed in a few cases after palsy of one of the muscles controlling the vertical movements of the eyes. Though this condition was first described by Caignet in 1873, this writer did not place quite the true interpretation on his observations, as he considered the ocular condition to be one of strabismus in association with hypermetropia, and credit should be given Wadsworth for first attributing torticollis to a paralysis of one of the eye muscles. The report of a case of this nature by this author may be found in the transactions of the American Ophthalmological Society for 1887, as well as brief mention by Risley of two cases of a similar character which had occurred in his practice. Since then five other cases have been recorded, all of which presented much the same features: paralysis of one of the vertical eye muscles and an obliquity of the head occasioned by spasm of the sterno-cleido-mastoid muscle.

Of the six reported cases (those by Risley are excepted on account of insufficient data) Nieden summarizes that the torticollis followed a paralysis of the superior oblique of the left eye, with obliquity of the head caused by traction of the muscles of the right side in three cases; in two the same muscle traction followed palsy of the right inferior rectus muscle, and in his case alone paralysis of the superior rectus of the left eye caused a contraction of the sterno-cleido-mastoid muscle of the same side. Graefe, however, questions the accuracy of Nieden's diagnosis, and states that the palsy in Nieden's case could not have been of the left superior rectus, but, rather of one of the muscles which pulled the right eye downward, i. e., the right superior oblique.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee. Report. H. V. Würdemann and J. A. Frank.

To these cases of torticollis of ocular origin the writer desires to add another.

CASE 1.—L. D., aged 9, was sent to the writer in May, 1900, by Dr. Alfred Hand, Jr., with the following note: "L. D. was a patient of mine in his infancy. Even at that early date I noticed a wry neck and once in holding the head straight, for the muscle was not permanently contracted, I saw a downward deviation of his right eye, which I thought might be the cause of his holding his head to one side. The case passed from under my care for several years, but seeing him again and finding the same conditions still present, I am referring him to you for an ocular examination."

On questioning the mother, it was elicited that a few days after birth the attending physician noticed a peculiar winking of the right eye and that shortly after this it was remarked that the head was drawn toward the right shoulder. Labor had not been unduly prolonged and forceps were not applied. The peculiar appearance in the right eye soon took the form of a distinct "cast," and the head was held constantly crooked. The muscles of the neck were never rigid but the head could always be straightened without difficulty. Recognizing the importance of early treatment, the child was taken to the Jefferson and later to the University Hospital, and notwithstanding that the general condition, which was somewhat impaired by rickets, improved under general medication, the wry neck did not respond either to the systemic treatment or the local application of electricity. When 22 months old, the child developed a retropharyngeal abscess, for which he was successfully treated by Dr. Hand.¹ Between the ages of 4 and 6 years, the child had frequent attacks of dizziness and on several occasions received severe falls from stumbling. Neither the mother nor the child remember his ever having seen double. When six years old he was given glasses, with marked relief to the dizziness and stumbling but without effecting any change in the axis in which he held his head. The writer first saw the child when he was 7 years old, and noted at that time the following condition: Child is apparently well nourished, but persists in drooping his head upon the right shoulder while the face is turned toward the left, the position being that which is occasioned by contraction of the right sterno-cleido-mastoid muscle. With the head in this deflected position the eyes are apparently on a level, but when the head is straightened, which can be done without difficulty, owing to the ready relaxation of the muscle, it is at once remarked that the visual axis of the right eye is turned down and that the patient fixes with his left eye. Vision and accommodation were normal in both eyes, the pupils were of equal size and responded well to light and accommodation stimuli. On account of there being crossed diplopia in the upper field, and the image of the right eye being higher, as well as the restriction of the movement in the right eye upward, and especially up and in, it was thought that the superior rectus muscle in the right eye was the muscle at fault. An operation to bring the visual axes of both eyes on the same level being refused the hypertropia was partially corrected by means of vertical prisms, but though these lenses have been persistently worn during the past two years, they have exerted no apparent influence upon the position of the head, owing partly to the fact that the prisms were inadequate to correct sufficient of the hypertropia to establish binocular vision and partly also to the fact that the deviation in the head had been of such long standing that secondary deflection had occurred in the spine, which tended to fix the deformity.

The accompanying photograph (Fig. 1) illustrates the position of the head and shows the left eye fixing while the right is deviated on a lower level.

4. RELATED BUT NOT COMPENSATORY MOVEMENTS.

The last class includes movements of the head and eyes which are abnormal and bear a direct relationship to one another without being compensatory. Cases of this class are those in which the anomalous movements

of both head and eyes are probably the result of a central lesion. The most familiar instance of this class is the simultaneous movements in head and eyes which occur in conjugate deviations after the involvement of certain portions of the brain, as, for example, cases of brain abscess, and not infrequently during the attacks in parietic dementia.

Another type of this class is the cases of head jerking associated with nystagmus which occur in young children—cases of so-called spasmodic nystagmus. In this disease the child moves its head rapidly, either from side to side or up and down—or at times with associated horizontal and vertical movements, while the eyes make rapid nystagmic movements. The direction of the head movements and those of the eyes may correspond, but this is not invariable, as the nystagmus may assume all forms and may be limited to one eye. Though, as a rule, synchronous movements of the globe are much more rapid than those of the head, at times the movements of the head and eyes are independent of one another. The nys-

Fig. 1—Torticollis due to hypertropia.

tagmus is aggravated by holding the head quiet and by making the eyes fix. In addition to the jerking movements, the head is not infrequently turned to one side or thrown back, probably in compensation for a faulty-acting eye muscle. for in addition to the nystagmus marked deviation in the visual axes, with strabismus, has been noticed in a large number of cases.

The absence of any pathologic changes which has been noticed in the few cases which have come to autopsy and the invariable tendency which these cases have to recover, has led Haddon to the assertion that the head and eye movements in this class of cases are due to an "instability of the motor centers above the nuclei, in the spinal cord and fourth ventricle, presumably the cerebral cortex."

It has been observed, however, chiefly by Randnitz and Caillé, that if the eyes are bandaged the motions of the head cease. Randnitz noticed also that the head movements were most influenced by the direction of the visual axes, that they ceased when the eyes were deviated

in certain directions and started up again as soon as they were rotated from this position.

Though there is ground from Randnitz's experiments that the head motion may be compensatory to an initial eye lesion, the nature of the affection is still in doubt, and it is probable that the ganglion cells which innervate the muscles of both head and neck are simultaneously affected by an exhaustion or irritation process. Rachitis and other nutrimental disturbances are common in this class of cases, and occurring as they do at the age when the association between head and eye movements is being perfected, probably act as the predisposing cause.

Under this class would fall also the wagging of the head which occasionally accompanies the eye movements in miner's nystagmus, both the head and eye movements being due to motor exhaustion of the cortical centers which govern the muscles of the head and eyes respectively. The writer desires to report under this class a case which is not very dissimilar from those of spasmus nictans.

FIG. 1.—Synchronous movements of head and eyes

CASE 2.—In June last a colored child, aged 8, consulted him at the Polyclinic Hospital. The following history was obtained: The child had always been healthy, but when it was about 5 years of age the mother noticed that its head moved from side to side, especially when regarding near objects, and queer movements were remarked in the eyes also. These movements were quite constant, were never very rapid or violent and ceased when the child was told to control them. Glasses had been prescribed, without exercising any apparent effect upon the movements of either head or eyes. At the examination it was noted that when the child walks about or when her attention is not attracted, the head is turned toward the left and slightly down, and very perceptibly rotated from side to side. These movements are regular and rhythmical and quite under the control of the will.

Inspection of the eyes reveals that they are in motion also and that there is a convergent strabismus of pronounced degree in the left eye. In contradistinction to the movements of the head, those of the eyeballs are vertical and slightly rotary, this being the more pronounced in the left eye. The nystagmic movements of the eyes are more frequent than

those of the head in the relationship of five movements of the eyeball to two of the head. The head and ocular deviations are well shown in the accompanying photograph (Fig. 2).

With the exception of a high degree of far-sighted astigmatism, both fundi were normal and vision could be brought to 5/7½ in each eye by the proper lenses. Notwithstanding this degree of visual acuity in both eyes, it was impossible to elicit double images, so that it could not be definitely ascertained which muscle or muscles of the left eye were at fault. As, however, the position of rest of the eye was constantly one of convergence, and as the upper and outer movements of the globe seemed to be most restricted, it was thought that the ocular condition could best be explained by a palsy of the inferior oblique muscle of the left eye, with perhaps a paretic condition of the superior and external rectus muscles.

The child was well-nourished and strong, playful and happy and gave no evidences of rachitis. There were three other children in the family, all of whom were healthy and none exhibited abnormal head or eye movements. With a view of determining the existence of any other nervous manifestations, the case was sent to the nervous department for examination. Dr. William G. Spiller, the professor in charge, reported as follows:

"The little girl, M. G., has no important symptoms other than the lateral movement of the head and the vertical nystagmus. I noticed that she shakes her head slightly from side to side at times, and that there is a tendency for the chin, more than the whole left side of the face, to be turned toward the left; a position that would be produced by the action of the right sterno-cleido-mastoid muscle. I have thought it possible that the vertical nystagmus—which seemed to me to be only in the left eye—might be the result of weakness in the ocular muscles to which you refer; and that the lateral movement of the head might have a similar cause, viz., slight weakness of the left sterno-cleido-mastoid muscle. I could not obtain any history of birth injury to this muscle, or of any subsequent injury, but it seems at least possible that if the left spinal accessory nerve were weak the sterno-cleido-mastoid muscle might be innervated incoordinately, and that in this way a lateral regular movement of the head might be established. This is offered merely as a possible explanation of the case. The knee-jerk is normal on each side. Sensation is normal and there are no hypersensitive zones."

THE PRESENT ASPECT OF THE TUBERCULOSIS PROBLEM IN THE UNITED STATES.

S. A. KNOPF, M.D.

NEW YORK CITY.

(Concluded from p. 131.)

After this general comment I will take up some of the states individually. Dr. William Duffield, Phoenix, Ariz., tells me that there is no board of health in the territory. Just think of it! Arizona, the place which is perhaps more sought and visited by consumptive invalids than any other, has no board of health, and consequently no laws nor regulations concerning tuberculosis in man. No circulars nor ordinances are issued. The town of Phoenix has an anti-spitting ordinance, but the law is a dead letter and has never been enforced. There is no sanatorium or special hospital for the exclusive treatment of tuberculosis in Arizona and no society for the prevention of tuberculosis. In his letter to me, Dr. Duffield lays particular stress on the sad fact that there is not a single place in the whole territory where the poor consumptive can receive shelter and treatment, and he also says "thousands of patients are sent here annually, hundreds of whom have but a few dollars when they arrive." But the climax of all this, it seems to me, is reached by the report that "the most stringent and rigid laws to combat bovine tuberculosis with the very best possible execution of the same are

carried out." How little importance seems to be attached in that territory to the danger of the propagation of tuberculosis from man to man and how much from animals!

From the report received from New Haven, Conn., I quote the following: "Twenty-five thousand dollars was appropriated to the Hartford Hospital to establish and conduct an experimental hospital for consumptives." Professor Lindsley very justly adds: "What the experiment is to be I do not know." It seems to me that the \$25,000 appropriated for the treatment of consumptives according to the already known methods which have proved so efficient would certainly accomplish a great deal more than this experimental hospital.

Another interesting point in connection with Connecticut legislation seems to be revealed in the following report, which says: "We had some laws to combat bovine tuberculosis, but they have been repealed." In connection with this state I must mention yet the report which came to me from Mr. Ward Bailey, clerk of the New Haven City Board of Health. On the inquiry whether there existed any circulars of instruction he said that he thought there were none. Yet the State Health Department of Connecticut which has its office in the same city from which Mr. Bailey sent me the report, has issued a most admirable circular, entitled "Consumption, Its Cause and Means of Prevention." The lesson which we learn from such a situation is evident, namely, that it does not suffice for a board of health to issue circulars, but it must also see that these circulars are widely distributed, and that at least all the employes of the health departments in the same state should know of their existence and be familiar with their contents. My question, "Is there any private or public institution for the exclusive treatment of consumption in your state or near your city?" which was addressed to the state as well as to the city board of health, was answered in the negative by both departments, yet there has existed for over a year in New Canaan, Conn., a private sanatorium for the exclusive treatment of consumption, of which Dr. M. J. Brooks is the physician in chief. Now I may be asked why should boards of health officers be expected to know of private institutions which treat consumptives? My answer is, they should know of all such institutions and should supervise them; leaving aside the value of the information which should be necessary for statistical or sanitary reasons, no hospital for communicable diseases should exist in any state without the knowledge of the board of health. The same criticism I must make in regard to the report I received from the State Board of Health of North Carolina. On the question, "What private or public sanatoria for the exclusive treatment of consumptives exist in your state?" I received the answer, "None." There are no less than three institutions in North Carolina, their existence having been reported by Dr. Ambler¹ of Asheville.

From the Health Department of the District of Columbia I received the following reply: "A letter is sent to such physicians from whom a death certificate has been received, giving the cause of death as tuberculosis, recommending the disinfection of the premises." This is doubtlessly a good recommendation, but I venture to say that if the recommendation would be extended so as to read: "The disinfection of the premises inhabited by a consumptive person is not only urgently recommended after death or removal, but also at regular intervals during the lifetime of the invalid," it would be

far more effective. The same suggestion I venture for Toledo, Ohio, where the report reads: "We are fumigating all houses of tuberculous people after death has occurred."

The secretary of the State Board of Health of Illinois did not know of the existence of the Illinois Society for the Prevention of Tuberculosis. Such a society should not only be known to the State Board of Health, but should be in permanent communication with it.

In contrast to this state of affairs I was pleased to learn that the secretary of the State Board of Health of Maine, Dr. A. G. Young, is at the same time the secretary of the State Sanatorium Association, and the Governor of the state is president.

From the state of Michigan, where such excellent work is done in general sanitation and in regard to the spread of tuberculosis from man to man, it is surprising to hear the following report, kindly sent to me by Dr. Baker: "If a case of tuberculosis in an animal is reported to the State Live Stock Commission, that commission is not legally bound to take action for the protection of the human species, but only to restrict the spread of the disease among animals." The destruction of tuberculous food products to prevent them from being consumed by men seems thus not to enter the province of the Live Stock Sanitary Commission.

From Missouri, thanks to the courtesy of the secretary of the State Board of Health, I learn that there is a special institution for the treatment of tuberculous insane, but nothing whatsoever is done for the sane tuberculous patients.

The Territorial Board of Health of New Mexico has a school law which makes it a prerequisite for all teachers of the public schools to furnish a physician's certificate that they are not afflicted with tuberculosis. The City Board of Health of San Francisco goes a little further and makes not only the same prerequisite to employment of teachers, but has also a provision to dismiss teachers who become afflicted with tuberculosis. The inefficiency as well as the injustice of such a law must be evident. A law which does not provide for the regular and periodical examination of school teachers can not possibly be effective in protecting a school from the presence of a consumptive teacher. So much for the deficiency of the law, but what about its justice? Is it right and just that school teachers who are discrete and intelligent and presumably educated in the simple means in preventing the spread of disease, are excluded from the public schools and the pursuance of their vocation, while any number of children who may be tuberculous are permitted to attend school, and, owing to their ignorance, infect their little comrades and perhaps the school teacher as well? I am not in favor of allowing consumptive teachers to pursue their vocation, for I believe their chances for cure are greatly diminished by the deficiency of good and pure air, characteristic of school rooms, but I honestly believe there is more danger from the spread of tuberculosis from child to child than from teacher to the children.

In Rhode Island the only circulars issued are those sent out with the bottles which are intended for the collection of sputum and those circulars which are returned with the positive report. In other words, there must be a demand for the examination of sputum before the board of health issues circulars of information. It would seem to me that the public should be informed a little earlier concerning the danger from infectious sputum. Dr. Swarts, the secretary of the State Board

1. "Public Sanitaria." THE JOURNAL A. M. A., Jan. 18, 1902.

of Health, very kindly called my attention also to a defect in Rhode Island's bovine laws. I gave the detailed report in its place, and here will only call attention to the fact that the farmer is not compelled to submit his cows to the tuberculin test until he wishes to, consequently he may utilize the animals for milk production until the last stages of the disease, and when they fail to give milk he can sell the diseased carcass to the state for half of its appraised value.

The State Board of Health of Tennessee has adopted resolutions concerning tuberculosis, anthrax and glanders in animals. They read as follows:

Resolved, That this board hereby gives notice that all persons are prohibited from selling milk, or other dairy products intended for human food, from cattle infected with either tuberculosis, anthrax (charbon) or glanders.

All persons are prohibited from skinning, selling, or otherwise making use of any part of any animal dead from anthrax (charbon) or glanders, and from throwing such dead animal into any pond, lake or running stream.

These resolutions are deficient in two points: First, they do not cover the danger which may arise from feeding animals with tuberculous products; for example, when calves or swine are fed with tuberculous milk or other tuberculous dairy products. Again, the second portion of the resolution does not include tuberculosis, and anyone may do with a dead tuberculous animal what he pleases.

The state of Texas distinguishes itself by an admirable enterprise. It has an agricultural colony for tuberculous prisoners. The result has been surprising. A large number of prisoners have been cured, and during the first year \$25,000 remained as net earnings of this philanthropic enterprise. There is no other state or private institution taking care of consumptives in the large state of Texas, the tuberculous prisoners alone are well provided for. This should give us much food for thought as to what to do with our consumptive poor in the earlier stages of the disease who are not criminals. A similar situation exists in Minnesota, where there is a special hospital for tuberculous prisoners.

The most striking and bold items of the many circulars I have studied are in the one issued by the young Washington State Board of Health. Here are a few of them:

RULES FOR THOSE WHO WOULD AVOID CONTRACTING THE DISEASE.

Summer and winter, women must wear skirts that clear the sidewalk. Avoid all kinds of fur or other soft trimmings around the lower border of dresses. Americans are expectorating animals. Note the filth, especially the spit on the sidewalks. Skirts drag through this, are taken home, dried, brushed and cleaned, and thus disease germs are introduced into the household.

Never put coin or other money into the mouth.

Do not forget that every case of consumption comes from some person or animal that has consumption. Do not spit in the cars, churches, theaters, sidewalks or other public places. If you do, the consumptive will do the same, and thus spread the disease.

As far as I could learn from the careful perusal of all the reports Boston is the only city which makes removal of a consumptive to a hospital compulsory in case proper care and isolation can not be procured for him at home.

From Pittsburg, Pa., we learn an important lesson in the need of combined action of state and city boards in the prevention of bovine tuberculosis. Dr. Matson very kindly writes me in this regard: "There are no measures, laws or regulations to combat bovine tuberculosis in our city, except what indirectly results from inspection of dairies within the city limits. This has had some

effect in driving the dairies outside, where they have been beyond our control until very recently."

From so large a city as New Orleans I received a negative reply to all my questions. The very amiable secretary, Dr. Sidney Theard, expressed his regret that tuberculosis has not received in his city the consideration it deserves. He mentions that a committee has been appointed to establish a state sanatorium, and he adds: "there the matter rests; doubtless the truth of science will eventually prevail." This shows that the fault does not always rest with the boards of health, but rather with the powers behind the throne.

While it is now universally recognized that the main source of the propagation of tuberculosis comes from man and the infection from beast next, the commissioner of health of Minneapolis writes: "All laws and regulations in effect in this city for the purpose of combating the spread of tuberculosis are confined to a rigid inspection of the cattle from which we get our milk supply. Every herd is tested once each year, and cattle found to be infected are condemned and killed."

To judge from the letter sent to me from the health officer of Louisville, Ky., he, like Mr Bailey from the New Haven city board, is not aware of the existence of an excellent circular issued by the State Board of Health in regard to the prevention of consumption.

RECOMMENDATIONS BY THE AUTHOR.

In presenting to you this report permit me in conclusion to suggest a few thoughts which have come to me during what I believe to be a careful study of the situation as it presents itself at this moment. There is no gainsaying that, compared with the situation of five years ago, we have made good progress in our anti-tuberculosis crusade. While a few states and cities have remained stationary, and some have even retrogressed, of the majority I can report progress. Anti-spitting ordinances have multiplied, thus showing that most health authorities consider indiscriminate expectoration the greatest source of infection. I heartily agree with this view, but I wish that our sanitary authorities would go a little further and not only prohibit expectorating in certain places, but also provide receptacles so that those who must expectorate may have an opportunity of doing so without offending others or doing harm. There are many ways of providing expectorating facilities, and I would not wish to be dogmatic in this respect. The ideal would, of course, be for everybody who is tuberculous, who has a chronic nasal or bronchial catarrh, grip, or is recovering from measles or pneumonia, or who chews tobacco, to use as a receptacle a pocket flask which would be unbreakable and could be used without attracting attention.

A CONVENIENT POCKET FLASK.

I take pleasure in showing you here a little model which, perhaps, answers all the requirements. As you see it is oval in shape and can be conveniently placed in a pocket. It is about $3\frac{3}{4}$ inches in height, its longest diameter is $2\frac{3}{4}$ inches, and its shortest diameter $1\frac{1}{2}$ inches. The opening is round and has a diameter of $1\frac{1}{2}$ inches. A movable funnel prevents the contents from soiling the cover, acting on the principle of the reversible inkstand. The flask is made of spring brass and is electro-nickel plated. Two seamless brass cups are welded together, forming the flask, to which the cover is firmly soldered and the funnel spun (seamless) with a flange fits exactly on the rim of the cup. The cover is closely fitted with an elastic rubber ring for the purpose of preventing leakage. There is a strong spring

catch which serves for opening and closing, and the flask can be manipulated with one hand by pressing

flask outside of the handkerchief the cuspidor can be used without attracting any attention.

Nickel-plated, oval shaped pocket flask. Manageable with one hand, with the thumb against the opening spring and closing the cover with the index finger. By the aid of a wire

The same, hidden in the folds of a handkerchief hook the funnel can easily be removed and the flask emptied. By placing the flask in the center of a mod-

Method of emptying the flask.

erate sized handkerchief, taking up the four corners and putting an elastic band around the neck of the

Round-shaped, nickel-plated pocket flask. Manageable with one hand.

Cheap metal flask with bayonet closure.

I also show you here a few other less expensive paper spit cups and pocket flasks which may well answer the purpose of distribution among the consumptive poor in dispensaries and special hospitals.

Blue glass sputum flask. Manageable with one hand.

Pasteboard sputum case, resembling cigar case

For the use in public institutions, in corridors and grounds I would recommend an elevated spittoon which has numerous advantages over the ordi-

Frame for Seabury & Johnson's spittoon cup.

Pasteboard cup for Seabury & Johnson's frame.

nary spittoon placed on the floor. The latter is unsightly, may be tipped over, and usually presents on its

rim or on the outside dried sputum which did not reach the receptacle proper. Having no cover these old-fashioned cuspidors allow animals and insects to get at the contents and thus help in the dissemination of the bacilli.

The stand of the elevated spittoon is 3½ feet in height and consists of iron tubing with a bottom plate which can be screwed on to the floor or fastened to a sunken board when used out of doors. The large cast-iron base, however, is in itself sufficiently heavy to prevent the spittoon from tipping over. On top of this

inches in height, supported by heavy tubing; the receptacle is made of heavy copper coated with pure tin on the inside, to the upper edge of which is screwed a perforated lead pipe which supplies the water for constant flushing. The receptacle is 9 inches in diameter, 5 inches deep, with a funnel-shaped bottom 3 inches deep, fitting into a 2-inch iron cylinder support, which also serves as a connection sewer, and this support is attached to a heavy cast-iron base. The lead-pipe water supply passes along the inside of the apparatus and can be attached to any hydrant.

Pasteboard sputum cup for bedside

Metal spit cup for bedside

tube is a round box of sheet iron, with a door which can be tightly closed. Attached to this door is a ring in which rests a blue or white enameled iron spittoon. Thus, when the box is opened the spittoon is drawn forward and ready for use. The top of the stand is provided with a rim to facilitate the placing of a flowerpot or other ornament. These elevated spittoons, only visible when in use, by their convenient height and easy manipulation make the deposit of the sputum into the cuspidor more certain than in the case where spittoons are placed on the floor.

Elevated spittoon, stand of wood—open.

Elevated self-cleansing street spittoon.

A UNITED STATES BOARD OF HEALTH.

Concerning the circulars of information, you have observed what a variety of views are expressed, and you will all agree with me that it would be a splendid thing if a committee with some authority, comprised of the leading sanitarians of the country, could come together and formulate such circulars of information. With

Elevated spittoon, entirely of metal—when in use.

The same, closed.

A similar elevated spittoon stand can be made of wood, which would make it considerably cheaper. (See figure.)

Proedohl's enameled iron spittoon can also be suspended at any height, and is particularly suitable for use in workshops and factories.

For street use, particularly in health resorts, I have devised the following receptacle, which might deserve the name, "public self-cleansing spittoon." It is 39

Proedohl's enameled iron spittoon, to be suspended at convenient height.

the vast difference in the variety and the deficiency of the laws concerning the combat of tuberculosis in man as well as in beast you are likewise familiar, and the only remedy I know of is a ministry of health in Washington—a United States Board of Health—to be in constant touch with all the states and city boards of health in the Union, with universal and effective laws

to combat tuberculosis in man and beast throughout the Union.

THE CONDITIONS IN CUBA.

How much good and effectual work our federal government can do in the combat of any disease has been shown in Havana. I shall not speak here of the simply marvelous way in which Governor-General Wood, whom we may justly call our own, since he belongs to the medical profession, has freed Havana from yellow fever; but I shall only report here the replies which have been received in answer to my inquiries concerning the work on tuberculosis. There is a military order directing that all cases of tuberculosis must be reported to the sanitary department under the classification of contagious diseases. Ten stations have been established in the different districts of the city for the collection of sputa, etc., sent by physicians. These are collected daily at 8 a. m. and forwarded to the bacteriologic department, a notification being returned to the physician, stating the result of the examination, and a record of the case is kept on file. If the patient is in a grave condition and is unable to be provided with the proper medical care, he is sent to the Municipal Hospital, where there are special pavilions, exclusively for incurable cases of tuberculosis. If the case is of a mild type, it is sent (provided there is room) to the Arroyo Apollo Sanatorium, which is now being established for the city poor for incipient cases. There are excellent circulars, tracts, orders, etc., relating to tuberculosis, issued by the sanitary department in Spanish and English.

There is a special pavilion on Pirotecnia Hill for the municipal poor, to which only bedridden cases of tuberculosis are admitted. There is also a sanatorium at Arroyo Apollo, ideally situated on high ground, about seven miles outside of the city of Havana, in the center of a farm of about fifty acres. These were established by the sanitary department. To the latter are admitted only incipient cases that have been previously examined by a special board of physicians. Besides these institutions there is the "Dispensario Especial de la Sanidad" (Special Dispensary of Health), with hours for consultation from 1 to 3 daily. Children and women, Mondays, Tuesdays and Fridays; men, Wednesdays, Thursdays and Saturdays. For employes in factories, unable to attend in the daytime, clinics are held Friday evenings from 8 to 10. This dispensary, which treats diseases of the chest exclusively, was also established by the sanitary department and is under its direct control.

There exists an Anti-tuberculosis League of Havana. The chief sanitary officer, Major Gorgas, and Dr. C. L. Furbush, acting chief sanitary officer, have been appointed by the society as honorary vice-presidents. The acting officers and members are Cubans. This society has done a noble work, and too much credit can not be bestowed on it.

A special board for bovine tuberculosis and glanders was inaugurated March 6, 1901, and is under the direction of the city government.

As a postscriptum to this admirable report, my friend, Dr. C. L. Furbush, the acting chief sanitary officer, writes me: "In addition to the work outlined, we have a special medical inspector for tenement houses and factories; one for cafes, restaurants, boarding houses and hotels, fondas and laundries; one for houses of prostitution, prisons, jails and the immigrant station; and another for milk and dairy products, markets, slaughter houses and bakeries; an auxiliary visiting board composed of laymen and physicians, who visit

bedridden cases that are unable to be provided for in the hospitals and who object going to the hospitals; to visit at the homes and to lend encouragement, provide medical attendance and improve the comfort and sanitary condition of their surroundings. By the above brief synopsis of the work being done in Havana you can readily see that we are all deeply interested in the question, and none more so than Governor-General Wood and Major Gorgas, the chief sanitary officer, who has covered himself with glory in his marvelous work during the past two years."

Thus you see that even the value of special tuberculosis dispensaries has been recognized immediately by the sanitary government of Cuba, and I regret to say that the importance of such dispensaries in the combat of tuberculosis is not sufficiently estimated in this country. Several of the large centers of population in France and Germany have now most active and well-equipped special tuberculosis dispensaries. Only the other day I read in the *Medical Review of Reviews* (April) that, thanks to the liberality of two French ladies who donated 800,000 francs, Paris will soon have another large municipal dispensary for the exclusive treatment of ambulant tuberculous patients.

THE NEED OF SANATORIA: THE OPPORTUNITY FOR PHILANTHROPY.

The great question of providing hospital and sanatorium accommodation for the thousands of consumptive poor and moderately poor can not be solved without the aid of philanthropists. Societies for the prevention of tuberculosis and sanatorium associations can do much to draw the attention of our public-spirited men to the urgent need of such institutions. But we physicians, family practitioners and specialists must make our influence felt whenever we have occasion, by word of mouth or by pen. What my own views on the duty of our philanthropists are in this respect I have recently made public in a little article, written for laymen and published in the *North American Review* for March. While gladly expressing my profound admiration and gratitude for all that has been done by our Carnegies, our Rockefellers, Vanderbilts, Morgans, Pearsons, our Helen Goulds, Phoebe Hearsts, Jane Stanfords, (Mrs.) Emmons Blaines, in giving us fortunes for universities, colleges and libraries, I think we as physicians may perhaps be permitted to call the attention of our American philanthropists to the great physical needs of the many suffering men and women of this country. There are now, perhaps, plenty of libraries and colleges, and even general hospitals, everywhere; but there is a scarcity of good, model tenement houses, where the average wage earner could enjoy a cheery, pleasant home without paying an exorbitant rent. In these model tenement homes, thoroughly sanitary, well lighted and well ventilated, a temporary sanatorium-treatment-at-home could even be successfully carried out if absolutely necessary, a thing which is an utter impossibility in most of our present tenement houses. There is a scarcity of public baths, which should, for a moderate price, be at the disposal of the people winter and summer, and for some hours in the evening. There is a scarcity of decently kept places of amusement, open all the year, where the laborer and his family may spend a pleasant Sunday afternoon and partake of non-alcoholic drinks. There is a scarcity of children's playgrounds, large and small parks.

There is a scarcity of hospital and sanatorium facilities for thousands of poor consumptives who could be cured if only taken care of in time. Sanatoria for con-

sumptive adults as well as seaside sanatoria for scrofulous and tuberculous children, are a crying and urgent necessity for the majority of our large American cities. Such sanatoria are schools of hygiene and sobriety, besides being institutions for the prevention and cure of tuberculosis. A half dozen sanatoria for the state of New York for example, one or two agricultural colonies for the very incipient consumptives, and a few special dispensaries in the larger centers would render thousands happy and healthy and make them breadwinners and useful citizens. As the conditions are now, the majority of these are doomed to a certain and lingering death; and if they are careless and ignorant of the necessary precautions, they will infect some of their own kin and neighbors. Could I but picture in these pages the dark, dreary rooms of the consumptive of our tenements, as I have seen them so often; could I but describe the sufferings of mind and body of these people, who must suffer and die, not because their disease is incurable, but because there is no place to cure them; could our generous and wealthy fellow-citizens but see for themselves these conditions; instead of more new libraries, universities and colleges, we would soon have better tenements, more playgrounds and parks for children, and an abundance of sanatoria, hospitals and other facilities for the proper treatment of our consumptive poor.

A NATIONAL TUBERCULOSIS COMMISSION.

Could this important Association, composed of well-nigh 30,000 representative American physicians, through a duly appointed committee, persuade the honored President of the United States and his illustrious advisors to create a national tuberculosis commission, such as now exist in several European countries, composed of the best sanitarians and most experienced physicians, who would formulate for us universal anti-tuberculosis laws, what good could not be accomplished! I am firmly convinced that with such an efficient corps of sanitary officers at the head of the various states and city boards of health, and such an array of philanthropists as we have in the United States the prevention as well as the cure of tuberculous disease here could be equally effective, if not more so, than in any European country. What is needed to attain this end is the combined action of a wise government, well-trained physicians, generous philanthropists and an intelligent people.

16 West Ninety-fifth Street.

Vaccination in England.—Since the unfortunate modification of the vaccination laws of England, enacted in 1898, very many children have been exempted from vaccination. The effect of this disastrous piece of legislation is already showing itself in more ways than one. Seventy English life insurance companies have required a renewal of their policies. Thirteen companies absolutely refuse to insure unvaccinated children, fifty-seven companies consider such persons as exposed to an extra risk, and refuse to pay the amount insured if the policyholder dies of smallpox, while only ten companies continue the old form of contract. Many public departments refuse to employ unvaccinated persons. The Duke of Norfolk (postmaster general), as a peer of the realm, voted for the conscience bill, but as a matter of public policy, does not allow unvaccinated persons in the postal service. The same is also true of the heads of the war and navy departments, each of which voted for the conscience bill, but allowed no unvaccinated persons in their branches of public service. The first lord of the treasury has adopted the same measure. In some quarters of the city landlords have turned out tenants who refuse to be vaccinated, and have placed signs on their houses bearing the inscription, "Not for unvaccinated tenants."

THE ARMY HOSPITAL AND SANATORIUM FOR THE TREATMENT OF PULMONARY TUBERCULOSIS, AT FORT BAYARD, NEW MEXICO.*

D. M. APPEL, M.D.
FORT BAYARD, N. M.

In the paper which I had the honor to present to this Section in 1900 I briefly described the establishment of the general hospital for the treatment of pulmonary tuberculosis in the military post of Fort Bayard, located in the dry mountainous region of southern New Mexico at an altitude of 6,040 feet. I then stated that all the buildings of the post, and the water system and sewerage, were very much dilapidated. These are now in good repair, entirely new and modern plumbing has been installed, but as yet no new buildings for the accommodation of patients have been erected. A glass solarium with steel framework (on the paradigm system) which was contracted for in June, 1901, is now nearing completion and will afford excellent protection from the high winds which occasionally prevail, especially during the spring.

The climate of Fort Bayard permits of comfortable outdoor life during the entire year. During the year 1901 there were 38 rainy days with a total precipitation of 8.94 inches. One hundred and ninety-eight days were perfectly clear, 151 partly cloudy and only 16 were wholly cloudy.

The mean maximum and minimum temperatures and the precipitation for the past decade are as follows:

Month.	Mean Max.	Mean Min.	Annual Precipitation.
January	52.81	24.41	1892.... 8.89 in.
February	54.23	29.85	1893.... 15.47 in.
March	60.41	31.12	1894.... 9.12 in.
April	68.02	37.31	1895.... 15.09 in.
May	77.46	45.05	1896.... 18.85 in.
June	86.91	53.24	1897.... 18.00 in.
July	82.75	55.56	1898.... 15.91 in.
August	85.29	57.53	1899.... 10.43 in.
September	82.07	52.27	1900.... 12.66 in.
October	70.84	41.45	1901.... 8.94 in.
November	60.70	32.15	
December	53.75	25.23	
General average....	69.60	40.50	13.34

In reporting our results from the incipience of the hospital to March 31, 1902, I will adhere to my original classification, excepting that, as three cases formerly reported "cured" have had a recurrence, I have substituted the term "clinically cured" for such cases in which all symptoms have disappeared and no reaction follows the tuberculin test. Those in which no bacilli are found in the expectoration after repeated examinations and, though presenting no evidence of active disease, still react to tuberculin, are classed as convalescent.

In my report to the Surgeon General for the period ending Dec. 31, 1900, patients were divided into three classes representing their practical division while under treatment: Class 1, cases afebrile without tubercle bacilli in their sputum; Class 2, cases afebrile with tubercle bacilli in their sputum, and Class 3, cases permanently febrile with tubercle bacilli in the sputum. The first class, those with no bacilli, have separate dormitories, and the third class, with permanent fever, are confined to the infirmary.

For the purpose of graphically representing on a diagrammatic chart the degree of involvement of lung tissue found on physical examination, cases are divided into three stages: 1, infiltration; 2, consolidation, and 3, excavation; corresponding to what are generally known

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee: Drs. Arthur H. Reynolds, George Cook and Heman Spalding.

as incipient, moderately advanced and advanced cases. In this classification is considered only the anatomic character of the involvement, irrespective of its extent or the area involved. On the charts infiltration is repre-

infiltration; D. I., dry infiltration; P. E., pleural effusion; H. P., heart's position.

Our patients are thoroughly examined every two months and also in the interim, when the symptoms indicate the existence of some intercurrent trouble.

The one death in the first stage was due to tuberculous appendicitis. Of the 9 deaths in the second stage 5 were from laryngeal or intestinal tuberculosis, 2 from empyema, 1 from rupture of an aortic aneurism and 1 from acute tuberculous pneumonia.

While, ordinarily, sanatoria for the treatment of pulmonary tuberculosis admit only about 25 per cent. of cases examined, as being suitable for admission, one of the purposes for the establishment of this hospital is to remove all recognized cases from the wards of general and post hospitals and from the Soldiers' Home at Washington, D. C., to prevent the propagation of the disease. Patients who are still in the service are sent to the hospital by order of the War Department, regardless of their condition or of their desire to come. They are not selected for treatment in a high altitude, and doubtless a small minority, even of those in the milder stages, would do better at a lesser elevation. A large majority do not realize the gravity of their affection and the importance of remaining until they are clinically cured. When they feel perfectly comfortable, with no pain or other subjective symptoms, it is usually impossible to make them understand the necessity of remaining longer under the essential restrictions of a sanatorium. In fact, very few Americans, especially of the class to which most of our patients belong, will voluntarily submit to a constant supervision and regulation of every detail of their lives, even to a lesser extent

bulant patients, and our results are much better in those who strictly comply with this rule. We administer it in the form of brandy, whisky, sherry and port, in moderate doses, only in the infirmary to patients with high fever and to relieve the extremely distressing debility in far-advanced cases.

The excessive use of alcohol is an important factor in producing a susceptibility to the disease by lessening tissue resistance, and our therapeutic efforts are directed to the development of this resistance in order to produce a tendency towards fibrosis. My observation has convinced me that in many cases its use retards and even prevents recovery. That alcohol and tuberculosis are antagonistic was formerly the general belief and is still the opinion of too many.

Nearly 80 per cent. of our patients come from the tropics, and in many of these, owing to the enervating effects of the tropical climate, the disease has made rapid progress before admission. Others in the milder stages in whom pulmonary tuberculosis followed malaria or dysentery, are very much emaciated on admission, and their improvement in nutrition and assimilation is often astonishing. Several have increased ten pounds in

Fig. 1.—Infirmary.

than is in vogue in the German sanatoria. Nearly all of our patients are discharged from the army in a few months after admission, but these can remain indefinitely if they so elect, as beneficiaries of the Soldiers' Home. Being no longer in the army they are free to leave at any time, and many of the most favorable cases, in which there is every reason to expect recovery, leave before such recovery is possible. Quite a number have returned, with their general condition much aggravated and their pulmonary lesion much advanced, which is of course, to be expected in a disease in which even a single indiscretion may often turn the tide from a favorable progress and lead to a fatal result.

Another factor which militates strongly against more favorable results is that a large majority of our patients have been addicted to the excessive use of alcohol, either occasionally or habitually. Despite all our efforts to prevent it, many succeed in surreptitiously securing a supply of liquor and become intoxicated. Though in some cases of tuberculosis moderate doses of alcohol are of benefit in the treatment of certain symptoms, I have found it advisable to absolutely prohibit its use by am-

weight, and one gained twelve pounds in one week. Patients are weighed every Friday and a report prepared of the gains and losses, if any, in each case.

Following is a portion of the report of April 4, the first Friday following March 31, 1902. The whole report for that week shows that 75 men gained, 48 lost and 32 showed no change:

TABLE SHOWING WEIGHT, GAIN AND LOSS FOR WEEK ENDING APRIL 4, 1902

to gently fill the lungs. Then following me in the exercise, at the command "one" they slowly inspire until the lungs are filled, and, resting a few seconds with the lungs inflated, at the command "two" rapidly expire. These exercises gradually increase the chest measurements and the expansion of the lungs and also cause the disappearance of temporarily collapsed areas, and I have hitherto observed no detrimental effects.

After the breathing exercise the patients scatter, some to receive local or special treatment and others to report for their bimonthly examination. The remainder walk or sit on the porches, where comfortable chairs and couches are provided, and engage in such pastimes as their fancies dictate. No violent exercise, such as bicycling, horseback riding, tennis or baseball are per-

mitted, but they are encouraged to play croquet, quoits or golf.

Patients are required to carry spit cups, consisting of common square tin frames containing a folded paper cup. I have devised a pocket cup which is made by patients, for the use of the officers and others engaged in light work, and which when made from suitable paper has been found very satisfactory.

Large cuspidors are scattered on the porches and in the recreation rooms. These are also of folded paper in a tin frame and enclosed in a covered box, placed sufficiently high above the floors so that the covers can be conveniently lifted. The paper cups are all burned in brick crematories, four of which have been constructed at convenient locations.

In considering the effects of altitude on the symptoms, it must be remembered that altitude alone, without the

hygienic regimen, is of little avail. No locality, however favorably situated, can confer immunity, as cases of pulmonary tuberculosis originate in the most favorable climate.

Life in the open air, which is the keynote of our treatment, is at first uncomfortable, but in our dry air, bright sun and clear sky a tolerance is soon induced. Though

we have frequent winds, the air is so dry that they are not objectionable, unless they are very high, such as prevail for a short period in the spring. At no time during the summer is the temperature uncomfortably high in the shade, and for the past two winters 13 degrees above zero is the minimum record.

Cough, except in advanced and laryngeal cases, soon becomes less distressing. Ordinarily it is easily allayed

by heroin, in the extensive use of which I have yet to see tolerance produced or a habit formed. In a few cases it is a decided soporific, but I have never observed any untoward effects. Even in advanced cavity cases severe cough is readily ameliorated and the cavities are soon found dry on physical examination.

In far-advanced cases with no laryngeal disease or emphysema, the cough rarely continues distressing and the cavities are usually found empty postmortem.

Further experience confirms my statement of two years ago, that hemoptysis occurs much less frequently than at lower altitudes. Nearly 50 per cent. of our cases have a previous history of hemorrhage, and in many it has occurred very recently before admission. In very few has there been a recurrence, and when recurring it is readily controlled, excepting in those with large excavations. In these latter cases it is generally fatal, if

of the disease. This tends to confirm the opinion that the most important element in the causation of hemoptysis in the milder stages is increased arterial tension or vascular congestion, rather than erosion of the vascular walls, and its lessened frequency in higher altitudes is probably due to lowered arterial tension resulting from diminished barometric pressure. Doubtless the prohibition of violent exercise is also a potent factor in its prevention.

Night sweats are rare and readily amenable to treatment. Laryngeal ulceration in the early stages has frequently been cured with simple palliative treatment and even when accompanying advanced and extensive pulmonary involvement has in some cases disappeared. Small pleural effusions are usually absorbed. If sufficiently large to require paracentesis for the relief of

the dyspnea, there is, as a rule, no recurrence if the effusion is sero-fibrinous. In the tubercular involvement of other parts, especially of the cervical lymphatics and of the ribs, the lesions have improved equally as well as those of the lungs.

The longer I observe the effects of treatment in a high altitude, the more I am convinced that a larger variety of cases are amenable to its beneficial influence than is commonly believed. Cases with extensive cavities in both lungs and in which pyrexia continued for several months after admission, have finally improved to such a degree that ultimate recovery is probable.

As shown in the chart of increase of weights extreme emaciation can not be considered a contraindication, nor does old age preclude a prospect of improvement in high altitudes. Two patients over 60 years of age have returned to the Soldiers' Home clinically cured.

We have carefully weighed the heart in all post-mortem examinations to determine whether this organ is congenitally small, as alleged, in those susceptible to pulmonary tuberculosis. We now have records of 73 autopsies in which we have found as follows:

Average weight of heart	292.2	grams.
Smallest heart	150	grams.
Largest heart	460	grams.
Number above average	41	
Number below average	32	

Investigations were recently instituted by Asst.-Surg. H. D. Bloomer and Contract-Surgeon J. J. Curry

of the hospital staff, on the condition of the blood in tuberculosis, with a view of ascertaining whether it would furnish any information of diagnostic or prognostic value.

Since commencing these studies they have made 58 examinations of the blood in 38 patients, of whom 17 were in the first stage, 8 in the second stage and 11 in the third stage, and 2 were cases of bone tuberculosis. Their records show marked irregular variations, not only in the number of red cells and leucocytes, but in the differential count.

In the first and second stage cases, while the average red cell count is practically normal, the leucocytes vary from 5,800 to 26,000, and the degree of leucocytosis, with few exceptions, corresponds with the extent of the pulmonary involvement. The eosinophiles were increased in three cases to 17, 22 and 27 per cent. respectively, careful search failing to reveal any assignable cause for this increase. In the third stage cases the hemoglobin and red cells were decidedly below the normal and the leucocytes greatly increased, averaging 28,374, the increase being almost entirely in the polynuclear neutrophils. The condition is therefore such as occurs in septic infection.

With the co-operation of Col. A. C. Girard, commanding the U. S. General Hospital, Presidio, San Francisco, we have also commenced a study of the effect on the blood of high altitude. At his request Contract-Surgeon Charles F. Craig, the pathologist of that hospital, is furnishing us a full report of the condition of the blood of patients immediately before transfer to Fort Bayard.

The average normal blood count at Fort Bayard is 6,000,000 to 6,500,000 red cells and 8,000 to 10,000 leucocytes. This is somewhat higher than that reported by Solly and by Campbell and Hoagland at Colorado Springs, and somewhat lower than that reported by Egger at Arosa, both practically at the same altitude.

Notwithstanding their tropical service and the fatigue of the long journey from the Philippines to Fort Bayard of patients transferred from the Presidio hospital, the average red cell count on arrival was 5,705,000, only slightly below the normal and an average increase of 1,604,000 above the count at the Presidio.

The hemoglobin average was 85 per cent., showing that it does not increase in the same ratio as do the red cells.

To Prevent Dust Raising.—An Austrian material for preventing the rising of dust on sweeping proves to be cottonseed oil. In a test at Vienna, it was found that floors oiled twice a year could be swept weekly without any whirling of the dust, and the material was recommended for all rooms where many people were received, as well as for laboratories, libraries, and other places to be kept scrupulously dust-free.—*Canadian Druggist.*

ANATOMIC TREATMENT OF FRACTURES OF THE FEMORAL NECK.*

C. E. RUTH, M.D.

*Professor of Descriptive and Surgical Anatomy and Clinical Surgery,
Keokuk Medical College, College of Physicians and Surgeons,
KEOKUK, IOWA.*

Six per cent. of all fractures being through the neck of the femur, giving as a result nonunion in the majority of cases with useless limbs, renders the subject of enough importance to justify its consideration in the light of all the latest attainable information.

There is nothing to be gained by attempts to differentiate between intra-extra-capsular and mixed varieties, for when not impacted their management to be successful can differ in no essential particular. Diagnosis is rarely attended with difficulty, the assemblage of symptoms being characteristic. This is, however, not true in the penetration or impaction cases when immediate

Fig. 1.—Fracture of neck of femur in Case 2. At 72 years of age, used 20 years afterwards. No perceptible shortening.

diagnosis may be impossible or methods to obtain it unjustifiable. In such cases the diagnosis will usually be cleared in a few days by loosening of the fragments or the impaction remains permanent and insures a good result barring complications in themselves serious. Our leading surgical authorities inform us that permanent impairment is to be expected, death is not uncommon and that nonunion usually results from fracture through the narrow part owing to impossibility of accurate coaptation and immobilization of the fragments. That this latter statement is erroneous I hope to demonstrate beyond a controversy.

The treatment which is here advocated is applicable to any solutions of continuity involving any part of the femoral neck and its connections to the shaft, to all

ages and physical conditions, gives as great comfort as any known plan, is easy of application, requires little time to adjust, requires no elaborate apparatus, gives no danger of pressure injury, places the fragments in apposition when properly adjusted and overcomes all displacing tendencies of weight and muscular action, which are the principal factors in preventing union and causing deformity or impairment of function. That bony union has occurred in all varieties of fracture of the femoral neck is no longer denied by well-informed medical men. That useful repair in the aged treated by the usual methods occurs only in a small per cent. is recognized by all physicians and attested by cripples from this cause in almost every community.

Twelve years ago I became impressed with the reasonableness of the method and results obtained by Prof. T. J. Maxwell in fractures of the femoral neck and have used the method in all my cases since and taught it to my medical classes. Dr. Maxwell has practiced and advocated the method for thirty-two years.

I published a report of seventeen cases in *THE JOURNAL* Aug. 26, 1899. Again at the St. Paul meeting last year I presented a supplementary report of eight cases, making a total of twenty-five. This paper was published

Figs. 2 and 3.—Vertical section of femoral neck fractured 20 years before. Case 2 of former report.

in *THE JOURNAL* Dec. 21, 1901. At the St. Paul meeting I also presented a specimen of a bone broken in a man aged 72 years. This was Case 2, R. P., reported by me Aug. 26, 1899. (Figs. 1, 2 and 3.)

It represents the result in the second case treated by Dr. Maxwell and gave its possessor satisfactory service for twenty years thereafter, though slight eversion gave constant testimony to its former solution of continuity. It also gives eloquent testimony to the possibilities in intracapsular fracture. The trouble is the result is too good to be believed by those who are unacquainted with Dr. Maxwell's skill in adjusting and retaining such fractures and do not understand the aid of the capsular ligament when properly utilized as a retaining force.

Perfect adjustment of the fragments must occur when traction is made in line with the normal axis of the femoral neck, provided the capsular ligament is not almost or quite destroyed, together with the surrounding muscles. This fact I have demonstrated by experiment on the cadaver.

Adjustment and retention of the fragments are easy and certain if the anterior strongest part of the capsule remains intact. Sufficient traction in the normal line of

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard

the femoral neck compels the capsular ligament to act as a close-fitting sleeve, to adjust and align the fragments; and if said traction be maintained the relation will also be undisturbed.

The tendency is for the lower fragment to fall behind and then be drawn upward and inward while it is usually rotated outward, causing an upward inward displacement of the lower fragment. It necessarily follows that the anterior part of the capsule falls across the upper fragment, which is frequently tilted forward, and if proper traction is made it will carry the upper fragment, now free of any muscular attachment, passively into line. The anterior part of the capsule, including the Y ligament, can always be depended upon, for it yields only to a force almost sufficient to produce evulsion. The action of the psoas and iliacus is normally that of a flexor with neutral or internal rotation. When a solution of continuity occurs in the femoral neck they immediately become pronounced external rotators. (Figs. 4 and 5).

Fig. 4.—Shows normal position, relation and line of action of the psoas and iliacus.

Fig. 5.—Muscle pushing itself or other soft parts between the fragments and producing external rotation.

They not only become external rotators, but often force the soft parts between the fragments. By so doing they make union impossible unless the impediment be removed, first by flexion, which raises the line of muscular action above the fragments. Then make and maintain traction on a line with the normal femoral neck, thus preventing tissue from being caught between the fragments.

In the fifteen additional cases which I have collected since the last annual meeting, I have given the names, as in my previous reports, of the physicians in charge and their addresses. Two of these cases have furnished us specimens, one of which should put forever at rest all questions as to the possibility of obtaining a result equal to that shown in Case 2. One proves the possibility of bony union with slight impairment of function in a case 81 years old treated by a novice.

The poor results usually obtained in treating fractures of the femoral neck have been explained in many ways, but most recent authorities have agreed that the important reason was imperfect adjustment and failure to maintain immobilization. It has been assumed that these difficulties could not be overcome. No greater error, I think, has been fostered by the profession for the manufacture of cripples. It may be urged that the direction of the breaking force may have thrown the distal end of the upper fragment backward, and entirely separated the posterior part of the capsular ligament, thereby leaving no tissue to direct the fragments into line. If, however, the directions, positions and relations of the quadratus femoris, obturator internus, obturator externus, gemelli, pyramidalis, psoas and iliacus is remembered, we will understand at once that the close relations of these muscles to the parts concerned will enable them to reinforce the capsule, however badly it may be injured, so that if they are all rendered taut by traction in the normal line of the femoral neck they will readily bring the fragments into position.

In non-penetrating fractures of the femoral neck the position of the fragments must depend largely on the position of the patient, the kind of retaining force and his own muscularity. Muscular action is of as much importance in determining results of fracture here as anywhere else in the body. This is due to the great number and power of the muscles passing over the fracture line and exerting their force at varying angles,

Fig. 6.—Illustrating lines of action of longitudinal and lateral extension and their resultant made necessary to overcome oblique action of the muscles. 1, Shaft line of longitudinal traction; 2, resultant; 3, line of lateral traction; 4, femoral neck.

the resultant of which is in line with the femoral neck. The sartorius, rectus, gracilis, semi-membranous, semi-tendinosus, long head of the biceps, tensor vagina femoris, vertical portion of the adductor magnus and portions of the gluteus maximus medius and minimus exert a powerful upward displacing force. This is further reinforced by the oblique upward and inward pull of the adductor magnus, longus, brevis and pectineus. The inward pull of some of these latter is very pronounced. Those which pull almost directly inward and rotate outward are the pyramidalis, obturator externus, gemelli superior and inferior, obturator internus, quadratus femoris and lower half of the gluteus maximus.

The method of treatment is as follows: Patient on the back, first flex the thigh on the abdomen to relax the psoas and iliacus and bring their line of action above the neck of the femur and so prevent them from in any way forcing soft tissue between the fragments. Then make extension while an assistant makes traction outward and raises the trochanter major to the same level as its fellow. Fifteen to twenty-five pounds weight is now to be used over a pulley to make downward extension on the leg. This is accomplished by

the ordinary Buck's extension with wide adhesive straps extending well above the knee. Binders' board or other material should now be molded to the internal, anterior and posterior aspects of the upper parts of the injured thigh, and around this a broad band of muslin or other material is extended by a cord through a pulley at the side of the bed, to which is attached a weight of from eight to sixteen pounds. This lateral pulley must be placed at such a height and have sufficient weight to overcome the tendency to eversion and to carry the trochanter to a level and of equal prominence with the opposite side. When this is done the direction of the pull will usually be outward, ten degrees upward toward the axilla and forward at an angle of about 45 degrees. The upward direction is to keep the padded binders' board on the inner side of the thigh, well up to the perineum and to make the resultant

the patient to slide toward the foot of the bed, and amounts to from ten to fifteen inches, according to the amount of weight required to overcome the muscular action. The side of the bed corresponding to the injured limb is also raised enough to overcome the tendency of the patient to be drawn toward the lateral pulley. The tilting required will be from two to five inches and will depend somewhat on the width of the bed. A single narrow iron bed is to be preferred. The anatomic method adds no complications to an already grave condition by operation or otherwise.

I have yet to know of a single patient with fracture of the femoral neck treated in this way who has complained of pain in the hip after suitable adjustment of the weights and pulleys, nor have they complained of

Fig 7—Anterior view Case 29

of the lateral and longitudinal forces fall in line with the femoral neck.

The binders' board is used on the inner side of the thigh to enable a wider bearing surface to be maintained, that no discomfort shall be caused by the connecting band to the pulley folding into a cord and tending to cut into the thigh. The usual precautions are necessary to protect the malleoli from pressure and to keep the patient clean. Bed and pressure sores can be avoided with reasonable care. The knee should be flexed every four or five days to prevent ankylosis, as neglect of this precaution has caused the patients more subsequent annoyance than anything else.

The counter extension for longitudinal and lateral traction is made by the patient's weight. The foot of the bed is raised enough to overcome the tendency of

Fig. 8.—Posterior view. Case 29

pain or other discomfort from the movement necessary to put the bed-pan under them, nor when raised to the sitting posture for cleansing, changing clothes, etc. Daily raising of these patients to the sitting posture, as above indicated, will not in the least disturb the fragments if the longitudinal and lateral traction is steadily maintained. These patients within one or two days can usually raise the hips themselves with the sound leg so that the bed-pan can be readily used. Four to six weeks of confinement, which is all that is usually needed to procure union, is not an element of danger in itself; besides, no plan of treatment or nontreatment so far devised can give greater if equal comfort and freedom of movement.

CASE 26—Mrs. Wagner, aged 69 years. Physician, Dr. Stanmeyer, Bonaparte, Iowa. Fell Jan 19, 1894, on icy side-

walk. Dr. T. J. Maxwell, Keokuk, saw the case in consultation. The usual signs of fracture of the left femoral neck were present. Shortening two inches—says Dr. Stanmeyer—foot everted completely, hip flattened, leg helpless and crepitus. Longitudinal and lateral extension was applied for seven weeks. No perceptible shortening. Weight of patient about 200 pounds. Soon regained complete and perfect use of the leg. Leg measured seven years later by Drs. Maxwell and Stanmeyer and no shortening was discoverable. Patient said: "I have had perfect use of my limb ever since recovery from the break, and have been able to walk without limp, halt or pain."

CASE 27.—Mrs. E. M. Dillemath, aged 68 years. Physician, Dr. G. L. Watson, Pomeroy, Iowa. April 26, 1897, patient slipped and fell on stone steps, striking right hip. Examination gave abnormal mobility, change in shape of hip, short-

shortening. Complained of no pain whatever after treatment was begun. Says: "I am the happiest woman on earth, because I never expected to walk, for I know of three cases of the same injury who were never able to walk."

CASE 29. Mr. George Royce, aged 81 years. Physician, Dr. Fordyce, Ainsworth, Iowa. Sustained fracture of the neck of the femur Jan. 28, 1901, by a fall upon the frozen ground. Shortening was two inches, distinct bulging on the anterior aspect of the groin and thigh, foot was everted and the slightest motion caused excruciating pain in the hip. Crepitus was elicited under chloroform. Buck's extension and counter-extension was applied at once. Adhesive straps extended above the knee. Between 15 and 20 pounds were used as extension weight. Pain was severe during the night in the hip; 10 pounds were then put on in lateral extension, which gave immediate and permanent relief.

Fig. 9.—Case 34.

ening one and one-half inches, foot everted, slight crepitus and severe pain. Diagnosed as intracapsular fracture and treated by Dr. T. J. Maxwell's method. Discharged June 20, 1897. Shortening one-fourth inch. Weight 168 pounds. Use of the injured limb as free, easy and satisfactory as the other. Does all her own work and walks long distances without discomfort. Had to be raised frequently while under treatment on account of suffocation from goiter. Dr. Watson says: "The fractured limb pained her but little after in position. I shall continue to use and advocate the use of this method for like cases as certain to bring better results than any other at present advocated."

CASE 28. Mrs. I. S. Nash, aged 72 years. Physician, Dr. A. John Droz, West Chester, Iowa. Feb. 22, 1899, sustained fracture of the left femoral neck, which was diagnosed by shortening, eversion and preternatural mobility with pain. Shortening one and one-half inches. Treated by extension and lateral extension. Discharged April 25, 1899, with no

Fig. 10.—Case 34.

REMARKS.—Treatment was continued for seven weeks. He regained perfect use of the limb and walked without crutches. Shortening of the limb was practically nil; never could make out one-fourth inch. Foot was slightly everted. Middle of following August had sunstroke, from which he never recovered, and he died Sept. 6, 1901. Specimen which I herewith present was secured postmortem by Dr. Fordyce. Fig. 7 anterior and Fig. 8 posterior view.

CASE 30.—Mr. C. Louder, aged 86 years. Physician, Dr. T. F. Jones, Fairfield, Iowa. Fractured the right femoral neck May 20, 1901. Two inches of shortening, eversion of the foot and crepitus were the evidences obtained of fracture. Treatment was begun at once and continued to May 25, 1901. A good, useful limb was obtained with one inch of shortening by extension in line with the femoral neck. Very little pain or discomfort was complained of.

CASE 31.—Mrs. S., aged 47. Physician, Dr. J. W. Holliday, Burlington, Iowa. Sustained fracture of the right femoral

neck by fall on a step. Diagnosis was made under chloroform, crepitus was obtained, there existed eversion of the foot and one and three-fourths inches of shortening. Injury sustained Feb. 8, 1901. Discharged April 25, 1901. Shortening three-fourths of an inch. Discomfort much less than usual and principally from the knee.

CASE 32.—Miss Pauline Miller, aged 56 years. Physician, Dr. A. C. Bernays, St. Louis, Mo. Fracture of the left femoral neck occurred as the result of a fall at night. Admitted into the service of Dr. Bernays April 17, 1901. Discharged July 23, 1901. Treatment was begun the next morning after the injury. Diagnosis of fracture was made by shortening of two inches with crepitus and eversion. Treatment by longitudinal and lateral extension. Treatment was discontinued after nine weeks. Shortening was one-half inch. Walks without cane in the house, but uses cane on the street. The treatment was comfortable to the patient.

CASE 33.—Mrs. R. Birlingame, aged 68. Physicians, Dr. J. F. Swarens, Beacon, Iowa, and Dr. C. C. Thompson, Keokuk, Iowa. May 1, 1901, patient had an attack of apoplexia, from which she partly recovered. On May 29, 1901, while walking across the floor she tripped and fell, producing fracture of the right femoral neck. With longitudinal and lateral extension the patient became rapidly comfortable, and remained so until July 16, 1901, when she sustained another attack of cerebral hemorrhage, from which she died one week later. She had good union with no shortening. Postmortem was not permitted.

CASE 34.—Mr. Rankin, aged 74. In feeble health from cerebral softening, sustained fracture of the neck of the right femur May 10, 1901. Examined by Prof. Geo. F. Jenkins and Dr. C. A. Jenkins, both of Keokuk, and by them found to have two inches of shortening and complete eversion of right leg and foot. The case was diagnosed as one of undoubted fracture of the femoral neck, and affidavits to that effect were sworn to by them before a notary public. Dr. T. J. Maxwell was called in the case about May 18 and assumed its subsequent management with Dr. C. A. Jenkins. The case was treated by extension, counter and lateral extension for four weeks, at the end of which time he was found dead in bed. He had complained of no pain whatever after the dressings were applied. Careful measuring of the limb failed to show any shortening whatever. Postmortem was made the next morning after death by Dr. T. J. Maxwell, at which the writer was present and the specimen secured, which I herewith exhibit (Figs. 9 and 10), showing line of fracture, only four weeks of treatment, union well advanced for the time, position is perfect, two inches of shortening had existed for one week before treatment was begun. The line of fracture is perfectly distinct in both sides and union has occurred, though too young to be absolutely solid as the unbroken bone. This case shows beyond a peradventure that repair may be had by this line of treatment in some cases which will show on the outside of the bone no signs of a solution of continuity, no shortening and no impairment of function even in the old.

CASE 35.—Mrs. Martha A. Gordan, aged 88. Physician, Dr. R. C. Ditto, Augusta, Ill. Sustained fracture of the right femoral neck May 17, 1901. Crepitation was obtained and was accompanied by complete eversion with shortening of one and one-half to two inches. Case was complicated with stroke of apoplexy with paralysis, which interfered with diagnosis. Treatment was begun for the fracture by extension, counter and lateral extension, May 23, 1901, and was continued for four weeks. Pain was relieved at once and patient remained comfortable throughout treatment. Shortening of three-fourths inch was the result. Owing to the paralysis and great enfeeblement of 88 years she has never been able to walk but a few steps. Patient is still living at nearly 89.

CASE 36.—Mrs. Peterson, aged 80 years. Physician, Dr. T. J. Maxwell, Keokuk, Iowa. Sept. 14, 1901, fell and fractured right femoral neck. Shortening was one and one-half inches, eversion was complete, flattening of the hip was marked and accompanied by complete helplessness. Was treated for six weeks with extension and lateral extension, at the end of which time union was found to have taken place with free and unobstructed movement of the articulation and no pain

whatever. Patient during treatment was frequently raised to the sitting posture to be cleansed and have clothing changed. Repeated measurements made by Dr. Maxwell and myself failed to reveal any shortening whatever. Raising to bathe her back and change clothing caused no pain and in no way seemed to interfere with repair.

CASE 37.—Miss Eva Marvel, aged 30. Physician, Dr. R. L. Casburn, Carthage, Ill., and Dr. C. E. Ruth, Keokuk, Iowa, consultant. Patient tripped, fell on the floor and sustained a fracture of the right femoral neck, which was at first supposed to be a dislocation, but under chloroform was, after a careful examination, found to be a fracture close to or at the head of the bone and apparently wholly within the capsule. Extension, counter and lateral extension was applied, which gave immediate relief to the pain which had previously been severe. Patient was first seen by me Oct. 24, 1901. The injury occurred six days previously.

Result: Examined and measured carefully by Dr. C. E. Ruth May 20, 1902. Can walk without assistance, but still uses one crutch most of the time. Shortening one inch. Motion perfect.

Fig. 11.—Case 39.

CASE 38.—Mr. Wesley Jarnigin, aged 62 years. Physicians, Drs. J. L. Robinson and W. H. Shaw, Monroe, Iowa. Fell on frozen ground Nov. 16, 1901, and fractured the left femoral neck. One and one-half inches of shortening with eversion and pain. Diagnosis made under chloroform. Treatment by extension, counter and lateral extension was begun at once. Patient was discharged Jan. 3, 1902, without shortening and with good use of the leg. Patient was immediately relieved of pain when the apparatus was adjusted and remained comfortable. Patient has plowed some with a walking plow this spring, which would be recognized as a thorough test as to the usefulness and capacity of the leg. He walks without a cane. Has a little soreness in the knee, supposed to be due to injury to the knee overlooked at the time or to prolonged extension of the knee without flexion.

CASE 39.—Michael O'Gorman, aged 52 years. Physicians, Dr. Frank B. Lucas and Dr. C. U. Collins, Peoria, Ill. Injury occurred Jan. 2, 1902. Treatment was begun January 3 and carried out in the county hospital at Peoria. Shortening two inches, eversion, preternatural mobility and crepitus. Fracture involved the left femur and was made under com-

plete anesthesia. Treatment by extension, counter and lateral extension was kept up until Feb. 12, 1902. Result: three-fourths inch shortening. Almost able to walk without crutch or other aid. Will have good use of the limb. Dr. Lucas says: "Patient suffered little discomfort after the Maxwell anatomic method was applied, and, I might say, less pain than any of my other six cases treated otherwise. No eversion of the foot exists at the present writing, April 30, 1902." I wish to state that Dr. Lucas made use of a very ingenious device to obviate the tendency to eversion by the adjustment of a bar across the top of the lateral pulley to the inner end of which the band around the upper end of the thigh was attached and to the other end of which the weight was attached. By this plan, should the patient move nearer to or farther away from the lateral pulley, the direction of the lateral pull was maintained at nearly an unvarying direction forward, upward and outward. (Fig. 11.)

CASE 40.—Adam H., aged 71 years. Physician, Dr. C. E. Ruth, Keokuk, Iowa. Fell April 26, 1902, on stone steps and complained of inability to move the leg and was in severe pain. On superficial examination I was undecided as to whether he had a severe bruise from fall or had impacted intracapsular fracture of the femoral neck, but inclined to the latter opinion, as marked flattening of the hip was easily demonstrated together with great pain on movement. Treatment was expected for five days, when the fragments began to disengage, shortening and eversion took place and patient was then removed to St. Joseph's Hospital and the anatomic method of

Fig. 12.—Illustrates method of applying longitudinal extension, counter and lateral extension.

treatment begun. Pain was at once relieved and patient remained comfortable save for a pleurisy which caused pain in left side for thirty-six hours. He was raised daily for cleansing, changing of clothes, etc., without pain. Large callus had formed by the tenth day. June 7, six weeks after injury, treatment discontinued, as union had occurred with good range of movement. Callus greatly reduced in size. Patient is able to sit up and is perfectly comfortable. Only one-fourth inch of shortening discoverable by repeated measurements by Dr. T. J. Maxwell and myself. Slight eversion exists. (Fig. 12.)

CONCLUSIONS.

Number of cases treated by this method so far reported, 40; number giving no demonstrable shortening, 16; number with one-half inch or less of shortening, 11; number with one inch or less of shortening, 10; number with flail limbs, no union, treatment abandoned in a few days, 3; total, 40.

Cases over 80 years of age, 9; union with ability to walk well, 5; non-union, 2; paralysis from debility with great age preventing walking, 2; total, 9.

Cases 70 to 80 years of age, 8; non-union, 0; good serviceable union, 6; died of brain softening, 1; union less than 2 months old, one-quarter inch of shortening, 1; total, 8.

Cases 60 to 70 years of age, 8; non-union, 0; good serviceable limbs, 8.

No failures to secure union under 80 years of age.

No failures to secure serviceable limbs in any case under 70 years of age.

Good serviceable union was obtained in 77.5 per cent.

Excluding 4 cases in which treatment was not continued 4 weeks gives serviceable limbs in 86 per cent.

Excluding cases in which treatment was abandoned within 4 weeks, death from intercurrent malady or in which the injury is too recent to report, gives good serviceable limbs in 100 per cent.

This Symposium on Fractures is to be continued by the papers of Drs. Thomson and Roberts, and the discussion on the three.

REPORT OF FOUR CASES OF SYPHILIS MISTAKEN FOR SMALLPOX,

WITH REMARKS ON THE DIFFERENTIAL DIAGNOSIS OF THESE TWO DISEASES.*

JAY F. SCHAMBERG, M.D.

Professor of Diseases of the Skin in the Philadelphia Polyclinic and College for Graduates in Medicine; Assistant Physician to the Municipal Hospital for Infectious Diseases.

PHILADELPHIA.

Of all diseases that protean and imitative malady syphilis is the one which is capable of most closely simulating smallpox. During almost every extensive epidemic of smallpox cases of the former disease are erroneously regarded as variola and are not infrequently sent into hospitals set aside for the treatment of this disease. This resemblance between smallpox and syphilis was noted by physicians several centuries ago. When syphilis was first recognized at the end of the fifteenth century it became necessary to distinguish it from smallpox which it occasionally resembled to a most striking degree. Variola was designated therefore small-pocks or smallpox, and syphilis, great-pocks or pox. (The word pock signified pouch or pocket, and was doubtless descriptive of the pocket left in the skin after the subsidence of the disease.) The same nomenclature was employed in the French language, *la petite verole* to indicate variola, and *la grande verole* or simply *la verole* to indicate syphilis. The error of confounding these two diseases is not confined solely to physicians of inexperience, but is from time to time made by those who have considerable acquaintanceship with smallpox.

CASES ILLUSTRATING THE RESEMBLANCE.

Since January, 1901, there have been treated at the Municipal Hospital about 1,900 cases of variola. Four patients suffering from acute syphilis were received during this period.

CASE 1.—C. H., a young woman of 21 years, was sent from another large hospital after having been seen by several physicians of repute. Nothing is known of the symptoms preceding the outbreak of the cutaneous efflorescence save that the patient was not sick enough to seek her bed.

The eruption appeared on April 14, 1901, as small pinhead-sized reddish papules, discretely scattered over the face, trunk and extremities. The lesions were most profuse on the back. In the course of two or three days small vesicles containing a little serum developed at the apices of the papules. On admission, April 25, some of the lesions presented small pustules with milky contents, others showed small crusts at their summits, but the vast majority were scaly.

The eruption remained more or less stationary for a week or ten days, when the patient was put on antisyphilitic treatment. During the period of her hospital stay she did not feel sufficiently ill to desire to remain in bed. About two weeks after admission she developed an iritis in the left eye which was in a short time followed by a similar condition in the right eye. After the disappearance of the eruption there remained reddish-brown stains and here and there on the back

oval pits. The patient had never been vaccinated, but secured a successful vaccination in the hospital.

CASE 2.—A colored man employed by a physician was sent into the hospital supposedly suffering with smallpox. On admission the disease was diagnosed as syphilis and the patient was placed in an uninfected building. He presented a generalized papular eruption over the face, arms, trunk and legs. On the following day he was discharged from the hospital.

CASE 3.—A young man, 20 years old, contracted a chancre about Sept. 1, 1901. October 21 he was examined by three skilful physicians, a professor of genito-urinary diseases, a professor of medicine and a city medical inspector. He was declared to have smallpox and was sent in to the Municipal Hospital. About a week prior to the development of the erup-

Fig. 1.—Case 1.—Papulo pustular syphilid sent to hospital as a case of smallpox.

tion the patient had slight headaches, chilly feelings, fever and night sweats. These symptoms, however, were not of sufficient severity to cause him to cease his work. He had been feeling languid and weak for a month or more preceding the appearance of the eruption.

At first sight the eruption would have passed for the efflorescence of a discrete smallpox. On closer inspection, however, it became evident that something was lacking in the picture, although it would have been difficult to express this deviation in so many words. The suspicion of syphilis was strengthened by the presence of the remains of the chancre.

The eruption, which was present on the face, trunk and extremities, consisted of small reddish papules, some of which had acquired vesico-pustular summits. In about ten days these had increased in diameter and were beginning to ulcerate be-

neath the crusts that had formed. A severe ulceration of the tonsils developed about this time. The patient was discharged from the hospital at the end of two weeks. By this time the ulcerative process had become pronounced. The lesions enlarged rapidly to the size of five-cent pieces, some indeed to the size of a silver quarter dollar. These became distinctly excavated and were covered with rupial-looking crusts. The soft palate was then attacked, extensive destruction of tissue taking place. The patient developed chills, high fever, sweats and rapid emaciation and was in imminent danger of death. Under the vigorous use of mercurial inunctions and a general tonic treatment, the patient improved and was again able to resume work. A couple of months later, although constant treatment had been kept up, the patient developed on the scalp two large ulcerating gummata. The malignancy of the disease in this patient is readily understood when such lesions manifest themselves scarcely eight months after infection. The point of interest in connection with this case is that a disease, later frankly syphilitic, should at the onset have presented such a strong counterfeit of smallpox as to have deceived several skilled and experienced physicians.

CASE 4.—A woman, aged 50, was sent into the hospital after having been carefully examined by several physicians. She presented on the face, trunk and extremities a generalized eruption consisting of lentil-seed-sized papules. She had had no distinct prodromal illness and was not at all prostrated on admission. On the left thigh near the groin was a round, firm, slightly elevated plaque about a centimeter in diameter with a superficially ulcerated surface. This was evidently the initial lesion of the disease which was diagnosed on admission as syphilis. The patient was immediately vaccinated and completely protected against the infection which surrounded her.

THE SIMILARITY BETWEEN THE TWO DISEASES.

It may at first thought seem strange that smallpox and syphilis should ever be confounded. On reflection, however, it will be seen that the diseases may have many symptoms in common. They are both infectious diseases, due, we may assume, to the invasion of the blood with a micro-organism. Each has a period of incubation, at the end of which there develop certain general manifestations accompanied by an exanthem and an enanthem. The resemblance may be still further accentuated by the fact that the variolaform syphilid is not rarely associated with and even preceded by fever and general aches and pains. It is particularly the pustular syphiloderm which is apt to be confounded with smallpox. This may be the first eruption to manifest itself or it may follow several months after the appearance of a macular or papular syphilid. The eruption at times may appear rather suddenly and pass through the stage of papule, vesicle and pustule in a surprisingly brief period of time. The lesions may be very firm to the touch and in other respects closely simulate those seen in small pox. Living, Jonathan Hutchinson and others have testified to the fact that in some cases the differential diagnosis is at the outset quite impossible. Hutchinson says: "The simulation of the variolous eruption by syphilis is the most marked example of syphilitic imitation. The papules are shotty to the finger, have depressed centers, affect the same region as variola and resemble it so absolutely that nothing but the history of the case can help the surgeon to a correct opinion."

HISTORY OF INFECTION WITH SYPHILIS.

In syphilis one can frequently obtain a history of infection and a description of the initial lesion. Indeed, the chancre or its remains may still be detected. Not uncommonly there are present associated evidences of syphilis, such as mucous patches, flat condylomata, ulceration of the tonsils, alopecia, etc. The variola-

form syphilid may develop after the disappearance of one of the earlier cutaneous outbreaks of syphilis.

DIFFERENCE IN ONSET.

The onset of the two diseases is, as a rule, quite different. The syphilitic patient will usually give a history of having felt weak and debilitated for some weeks. If fever precedes the eruption it is not very high and is not accompanied by severe prostration. When the rash appears the patient will usually call on the physician at his office or at a dispensary. We do not note that sudden illness which precedes unmodified smallpox. In this disease two or three days before the efflorescence appears the patient experiences a chill followed by a rise of temperature often to 103, 104 or 105. There are severe headache, backache, vomiting or nausea, vertigo, general pains and severe prostration. The patient instead of calling on the physician sends for him.

It must be remembered, however, that patients suffer-

Fig. 2—Large papular syphilide suspected of being smallpox during the prevalence of an epidemic of the latter disease

ing from an attack of smallpox that has been rendered mild through previous vaccination or through a certain degree of natural insusceptibility, often experience but slight initial symptoms. On the other hand, in rare cases, syphilis may produce an initial illness which strongly counterfeits that of smallpox. The following is a case in point:

W. J., a colored man, 24 years of age, developed a chancre about Nov 1, 1901. Thursday, December 26, he was taken sick with fever accompanied by great thirst and heat of skin, severe headaches and general pains. Following this, chilliness, fever and vomiting at night. He stopped work and went to bed on Thursday. Three days later an eruption developed. He rose from his bed January 2 and on the following day presented himself at the skin department of one of our hospitals. At this time he was covered with a profuse eruption consisting of pinhead and larger sized papules. The eruption was most copious on the back. The lesions were apparently at the mouths of hair follicles, and showed slight follicular umbilication in the center. The face showed lesions around the border of the

hair, on the forehead and in the bearded regions. The eruption was also present on the arms above the elbows and on the thighs. None was present on the wrists or hands. On the prepuce was a hard cartilaginous chancre, ulcerated in the center. Smallpox was at once excluded by the fact that the lesions had not developed to the stage indicated by the duration of the eruption.

SUDDEN ERUPTION IN SMALLPOX.

The appearance of the eruption in smallpox is rather sudden. Ordinarily in 48 hours the full complement of lesions is present. In syphilis the eruption may continue to come out for a number of days; in other words, the lesions appear in crops. It must be admitted, however, that in some cases of modified smallpox the appearance of the lesions may, in some cases, be spread over a period of three or four days.

It is stated in a prominent treatise on smallpox that enlargement of the inguinal glands may be regarded as a manifestation pointing to the diagnosis of syphilis. The writer has on many occasions examined the inguinal glands in smallpox with the view to their comparison with those of syphilis. It may be stated that the superficial glands are, as a rule, considerably enlarged in smallpox. The presence of a generalized or localized adenopathy is therefore of little or no diagnostic value.

DISTRIBUTION OF ERUPTION.

The distribution of the variolaform syphilid may be identical with that seen in smallpox. Frequently, however, there are variations observed. The pustular syphilid may involve the trunk more copiously than the face. This would be excessively rare in a well-marked smallpox. The dorsal surfaces of the wrists and hands are nearly always involved in smallpox, but may escape entirely in syphilis. The palms of the hands and the soles of the feet are always involved in severe smallpox. In moderate eruptions they nearly always present some lesions; in mild cases of varioloid they may or may not escape completely. The pustular syphiloderm affects the palmar and plantar surfaces with the greatest rarity. In Case 4 the writer observed a single lesion on the palm of one of the hands. In another case a deep-seated pustule was seen on the lateral surface of the sole of the foot. All writers are agreed as to the great infrequency of the lesions of the pustular syphiloderm on the palms and soles. This is in striking contrast with the papular syphiloderm which commonly involves the palmar and plantar surfaces.

THE CHARACTER OF THE ERUPTION.

In the beginning the eruption may be so nearly identical in the two diseases as to make a diagnosis from this symptom alone quite impossible. It will be noted, however, that the efflorescence of smallpox presents a much greater degree of uniformity, a more uniform development of the lesions over the body than does syphilis. (It should be remembered, however, that the lesions on the face in smallpox are, as a rule, a little in advance of the eruption elsewhere.) Syphilis is characterized by an essentially multiform eruption: it is not uncommon to find small pustules, large pustules and papules interspersed and these in varying stages of evolution and involution. The lesions of syphilis may be grouped in the form of circles or segments of circles, particularly about the border of the hair, the commissures of the mouth, etc. The vesicles and pustules of syphilis are usually conical and involve merely the summits of the elevation. They never become full and globular, filling the entire lesion, as do those of smallpox. The pustules of syphilis may remain small or may

later grow to large size, drying into brownish or greenish crusts. Beneath the crusts considerable ulceration not uncommonly occurs, according as that is slight or severe there will be seen on detachment of the crusts a reddish brown pigmented oval or round stain or an excavated ulcer. The latter heals with the production of depressed scars. The superficial and non-ulcerated pustules frequently exhibit at their base a scaling colarette.

THE COURSE OF THE ERUPTION.

The course of the syphilitic eruption is relatively chronic compared with that of smallpox. The lesions of variola undergo a striking change in a few days. The syphilitic efflorescence is indolent and presents, as a rule, no decided alteration of appearance within this period of time. By the sixth or seventh day in smallpox the lesions develop into these full, round, hemispheric, grayish or yellowish pustules, which are so characteristic of the disease.

Finally, to the physician who has seen much of smallpox, there is a something in the picture, an impression given by the *ensemble*, which, while not definable in language, is nevertheless a subtle aid in the diagnosis. Whenever the diagnosis between syphilis and smallpox is in doubt, observation of the progress of the eruption for a period of 24 or 36 hours will usually make clear the nature of the disease.

DISCUSSION.

DR. W. S. GOTTHEIL, New York—In spite of the distinguishing points to which Dr. Schamberg has called attention, there are occasional cases in which it seems impossible to differentiate syphilis from variola. During a smallpox epidemic that occurred some years ago in New York a number of patients suffering from the disease were sent to the venereal wards of the old Charity Hospital with the diagnosis of lues, the mistake being exactly the opposite to the one here recorded. These cases are often seen only once, and a diagnosis must be made; and in doubtful cases I would place much reliance on the fact that in variola the lesions are all of about the same age and in the same stage of development, while in the pustular syphiloderma there are younger papular efflorescences interspersed with them. In some cases, however, it is quite impossible to make an absolute diagnosis immediately.

DR. A. RAVOGLI, Cincinnati—The point that the distinction between syphilis and smallpox may be made by the history or presence of a chancre can help the diagnosis, but in cases of syphilitics taking smallpox this sign would be of little value. I find that not much attention has been called to the condition of the mucous membranes of the mouth, and this is one of the symptoms on which, when present, I place a great deal of reliance. In smallpox we have lesions of the mucous membranes of the palate, which is especially seen at the time of the prodrome, a few hours before the eruption appears in form of small, reddish points or of small vesicles, scattered over the soft palate. In syphilis we have an entirely different condition of the mucosa of the mouth in form of erythema faucium and mucous patches, which can be considered one of the best characteristics distinguishing between smallpox and syphilis. I have been called in consultation by health officers of small cities or by physicians who had quarreled between themselves, some saying it was a case of smallpox and some saying it was a case of syphilis, and in order to avoid a lawsuit they wanted it decided right away. I have found it rather difficult to decide in so short a time whether it was smallpox or syphilis. The condition of the mucous membranes has sometimes helped me out in those doubtful cases. The fever, too, is a good sign. In syphilis the fever is only accidental and is very mild, but in cases of smallpox usually it is of a more severe type, preceding for a couple of days the eruption, which comes much quicker than any eruption of syphilis.

DR. W. T. CORLETT, Cleveland—I agree with Dr. Ravogli that sometimes to make a differential diagnosis on the spur of

the moment is indeed a difficult task. In two instances within the last six months I have been forced to make a snapshot diagnosis from insufficient data; in both a few hours revealed the error of this practice. In another case the physician in attendance gave the clinical history as follows: The man had been ill four days, had been sick and vomited, had a rise of temperature of four degrees, had irregular pains in his shoulders and back; and there was a distinct eruption, first appearing on the back, and when I saw the patient a few days later it was appearing on the anterior aspect of the body. It appeared to be a typical case of variola, and after studying the case for more than 24 hours we found a new group of vesicles appear. But the eruption was not evanescent, and in a few days slight induration could be detected, when it looked like variola. This was excluded within a few days, and it was not until nearly a fortnight had elapsed that a positive diagnosis of semi-malignant syphilis was made. As Dr. Ravogli has said, the multiform character of the lesions with the tendency to induration at their base is an important feature to take into consideration in making diagnosis.

DR. C. W. ALLEN, New York—I recall a case in which the history and presence of chancre was not present to guide us, but there was an extensive phagedenic ulceration of the prepuce and glans penis that had undermined the skin of the penis up to or almost to the pubes. The nature of this phagedena was not known, but we discovered groups of pustules all over the body, the ears, face and forehead and all over the back. It looked very much like smallpox and there was nothing to show that there had ever been a chancre present. We had suspected that the phagedena was probably of chancroidal origin. We referred the case to the Board of Health, and after a very careful analysis of the case they isolated the man. They did not want to send him to the smallpox hospital that day, but they thought the case was thoroughly suspicious, and they kept him isolated two or three days—it turned out to be syphilis. That was the first eruption the man had had, and the lesions were all pustules, with no multiformity of lesions. They were all of the same nature.

DR. H. W. STELWAGON, Philadelphia—I have met with one instance in which a positive diagnosis between syphilis and smallpox could not be made for a period of nearly three days. This case was also seen by one of our best clinicians; it was seen by a specialist in genito-urinary diseases, and by other physicians, and for almost seventy-two hours not one was willing to venture an absolute opinion, but it turned out to be a case of syphilis.

CONCERNING SOME VACCINAL ERUPTIONS.

HENRY W. STELWAGON, M.D.
PHILADELPHIA.

The discussion which followed this address at the Saratoga meeting was, by an error, omitted last week (THE JOURNAL, November 22, p. 1291). It is as follows:

DISCUSSION.

DR. M. B. HARTZELL, Philadelphia—This subject is one which has been very much neglected. There is no doubt that eruptions of various kinds may follow vaccination, some of them at times serious, perhaps even dangerous to life. I think it would be worth while for those interested in diseases of the skin to study this subject carefully. The whole subject is in a good deal of confusion, and I regret to say that many physicians, as well as the laity, are inclined to regard vaccination as responsible for all sorts of things. Personally, it has seemed to me unscientific that vaccination should be regarded as a cure for anything or a preventive of anything but variola, yet the layman is convinced that vaccination works some change in the blood which alters the susceptibility to diseases of the skin. People have come to me and desired to be vaccinated because they thought it would cleanse their blood. The profession itself is largely to blame for some of these ideas because there are many physicians that either tacitly or in so many words declare that vaccination is responsible for all sorts of things. It has happened frequently that patients have

been referred to me with the statement that their eruptions were due to vaccination, when it was readily shown that vaccination was blameless. I think we owe it to ourselves and the general public to learn just what are the exact facts.

DR. H. G. ANTHONY, Chicago—Of the bullous eruptions which occur after vaccination, I believe that impetigo contagiosa bullosa is one of the most common. Exactly how the disease is contracted, I do not know, but it is most frequently observed where there is the ordinary form of impetigo in the family at the time of vaccination.

I am sure the dermatitis herpetiformis may follow vaccination. Pusey describes an undoubted case. I have observed one in which the patient had repeated attacks; each attack was preceded by severe itching for 24 to 48 hours. The disease was controlled by arsenic in a most remarkable manner.

DR. M. L. HEIDINGSFELD, Cincinnati—I have had some cases of eruption following vaccination and my conclusions have been a little different from those of Dr. Stelwagon. The contents of those bullous eruptions will promptly produce vaccinia, and that in some measure will show that the eruption has some relation to smallpox or variola. As far as I was able to determine these cases of bullous eruption occurred in one of two different ways. They occur either promptly after vaccination, as in ordinary eruptions of different types, or it is the reaction of the system against the intoxication of vaccination.

DR. JAY F. SCHAMBERG, Philadelphia—The allusion of the chairman to vaccinal rashes is most apropos at the present time, owing to the widespread prevalence of smallpox in this and other countries. More vaccinations have probably been performed in the United States within the past two years than in the previous fifteen years. The etiology of vaccinal eruptions is better understood if we regard vaccinia as a mild infectious disease complicated by the presence of a cutaneous wound. Many infectious diseases, such as measles and scarlet fever, are capable of determining the outbreak of an eczema, a psoriasis or some other dermatosis in individuals predisposed to these affections. Vaccinia may act in a similar manner. It is probable that many of the bullous eruptions which occasionally follow vaccinia are due to the accidental introduction into the system of extraneous bacteria or their toxins, which may gain access through the cutaneous wound. There is a tendency, much to be deplored, on the part of physicians as well as laymen, to attribute to vaccination any eruption which may happen to develop after its performance. In many of these cases the eruption manifestly bears no relation to the vaccination save a chronologic one. I have recently seen two patients who each attributed an eruption to a vaccination performed three or four weeks previously. In both instances the eruption proved to be an extensive ringworm which was traced to contact with domestic animals.

DR. A. RAVOGLI, Cincinnati—We find that in the inoculation of the vaccine virus the physician is responsible for the introduction of other morbid germs. At present, as we are using the virus taken directly from the cow, the inoculation of syphilis, together with the vaccine virus, is not so common. I remember many years ago a small localized epidemic of syphilis which had its origin from the inoculation of vaccine virus contaminated with syphilis, taken from a syphilitic child. The most interesting infections to-day are from the different staphylococci and streptococci, which often the patient himself inoculates on the little wound resulting from the vaccination by scratching with his finger nails. Not long ago I was called to see a boy affected with a bullous erysipelas covering nearly the whole body, as the result of vaccination. The boy died in consequence of this erysipelas. In this case we do not have to incriminate the vaccine virus as the factor of the erysipelas, but the accidental inoculation of the streptococci, probably by the boy himself. Many cases of vesicular and bullous eruptions in the form of dermatitis consequent to vaccination have occurred in my practice, which I have considered the result of staphylococcus inoculation. The pustula following the inoculation of the vaccine virus is accompanied with intense itching, and, in order to satisfy the pruritus, children will scratch with their finger nails. The finger nails take quantities of staphylococci from the little wound and scratching in other parts inoculate the pus-producing germs, which cause a form of derma-

titis of the mentioned types. In some cases I have seen reinoculated the vaccine virus through the finger nails in different parts of the body. In a case of an adult he had inoculated the tip of his nose.

In reference to other diseases like psoriasis, etc., I have never had occasion to see cases of the kind following vaccination. I find we have nothing to be afraid of from vaccination if we pay careful attention to aseptis, and enforce rules strictly.

DR. W. T. CORLETT, Cleveland—I think it is of special importance to bring this subject before a body of men such as are here to-day. The public have an idea that almost anything that follows vaccination, whether it comes a few days, weeks or years after, is due to vaccination. We all, in our practice, have had such instances occur. The question that occurs to me is: Do we have more contagious manifestations at the present time with bovine virus than was formerly the case with arm-to-arm vaccination? When I began to practice medicine arm-to-arm vaccination was the rule, whereas the virus is now derived from the cow. So far as my experience goes, mothers bringing in their children and adults presenting themselves with eruptions, eczema or psoriasis, will claim the disease is due to vaccination. Without almost any exception, as far as I am able to find out, there has been no connection between the diseases present and vaccination. In a few instances I have seen a general bullous eruption following vaccination, which I have regarded as the ordinary impetigo. At any rate, I have seen no difference between that and the ordinary impetigo and have so regarded it. There is one point that ought to be brought out. We often produce local effects in vaccination that do not give rise to any serious disease of the skin, but affects the spot locally. This sometimes gives rise to a great deal of apprehension. People oftentimes regard themselves immune from smallpox if they have a large scar, well defined; they think they are well vaccinated. Such vaccination does not prove anything so far as protection against smallpox is concerned. It has given rise to inflammation resulting in ulcer and the principles of vaccine may be entirely absent.

In regard to diseases following vaccination, such as psoriasis, I believe we may have them following vaccination. A woman presented herself at the hospital, who was declined admission on account of psoriasis, but it was found the eruption was caused by the rubbing of her clothing. We do not have psoriasis produced by irritation. I would not regard the process of vaccination as contributory.

DR. C. W. ALLEN, New York—I think a representative body like this should decide a few points in the matter for the guidance of those who are interested from the practitioner's standpoint. One is that we can have a great variety of complications of vaccination in the nature of skin diseases of various kinds which might occur at any other time, vaccination being merely an incident. Aside from those we can have a more or less generalized vaccinia, due to an accidental inoculation by the subject's finger nails carrying the virus to other regions of the body, and generally it is unwise to vaccinate a child who has pre-existing eruption of eczema, impetigo or generalized acute eruption, especially of pruriginous nature like scabies. I have seen multiple vaccinia scattered over the arms, behind the ears, about the face and on various regions of the body, which simply meant that the child had scratched and transferred the vaccinia to those regions. I have been called in consultation to see a man who had an enormously swollen face, with the eye closed and features distorted. The diagnosis was in doubt. Investigation developed the fact that he had taken care of a child that had been vaccinated and had accidentally inoculated himself on the upper lip. It has happened to physicians that they accidentally inoculated themselves on the tip of the nose, and if there is anything you want to avoid doing it is that. It makes an enormous swelling and is one of the worst things that can happen to a self-respecting physician. I saw a physician last year who had accidentally inoculated himself in the eye, in breaking off the tip of the vaccine tube, and he almost lost his sight, while for months he had a terrible time from it. You can imagine what vaccination of the conjunctiva would accomplish. When we are confronted with a

more or less generalized vaccinia-like eruption I think we should admit at the present day from the evidence referred to in the paper that it is a systemic effect of vaccination and that when we have a bullous eruption such as has been described, it is probably true vaccinia. When the American Dermatological Association met in New York a few years ago I took a little child to the meeting to show this form of generalized bullous vaccinia, and many of the members said it was the first instance they had seen. I think we have these three distinct classes of eruptive disease, and then I believe in the first class we may include dermatitis herpetiformis, which, although it resembles impetigo contagiosa, it may also resemble pemphigus, but continuing perhaps for several years, each being preceded by inflammation, a condition of malaise, restlessness, and itching of the skin. These symptoms also relate to dermatitis herpetiformis. I believe that dermatitis herpetiformis may have many causes and vaccination may be one of them.

Dr. E. L. Cocks, New York—I am satisfied that one-tenth of all the cases we see are due to the operator himself, and I am thoroughly convinced after a series of thirty cases of children between the ages of 3 and 9 on whom I was surgically experimenting. I had the arms cleansed with soap and ether, then vaccinated the child, and immediately sealed the wound with collodion. That was kept on until it dried, about half an hour, and then covered with a bandage. The highest temperature I had in those cases was 99 degrees, and on the seventh day I examined the arms. They were all successfully vaccinated and the vesicles were typical in each case. I had not one case of any eruption mentioned here this afternoon. It seems to me if we properly vaccinate the patients that come to us and advise them to take all antiseptic precautions we will not see all sorts of diseases and eruptions as mentioned here this afternoon. But as long as a physician will vaccinate a patient without any precautions at all, taking the needle out of a case, scratching the arm and rubbing in the virus and then letting the patient go before it is dry, we are going to have these manifestations.

THE PLACE AND IMPORTANCE IN THE COLLEGE CURRICULUM OF PHARMACY

J. ALLEN PATTON, B.S., M.D.

Assistant Professor of Materia Medica and Chemistry, Rush Medical College.
CHICAGO.

The medical college curriculum is a course of didactic and clinical study laid out by experienced medical men and intended to take the medical student over such work as will best prepare him to enter on the practice of medicine and surgery. Like all plans or outlines intended to guarantee a structure that will withstand the assaults of time they require a proper foundation, and this we may call the preliminary education of the student; then, upon this foundation the medical curriculum should rise with the elementary years in medical schools filled with those broad and ever-broadening basic studies upon which the practice of medicine was founded, and from whose increasing breadth and depth the modern practice of medicine has received its nourishment, and is continuing to receive a daily stimulus.

PRELIMINARY EDUCATION.

The common school education, while never considered broad enough, was formerly thought to be enough for a student to have before entering upon the study of medicine, but as the study of medicine has broadened the better schools have increased their entrance requirements, and a few have demanded college degrees. Leaving out the entrance demands of the various colleges, let us see what the science of medicine and the limits of the better medical schools would require before entering on their work. Thorough drilling on the three R's is demanded before going forward in the com-

mon schools, and their elaboration into the higher literature, logic and composition work, algebra and geometry of the high schools and academies, is preparatory to the study of the more diversified fields of literature, mathematics and natural sciences of the colleges and universities.

No student of modern medicine can deny the necessity for thorough instruction in the use of the English language, a fair knowledge of Latin and preferably a reading knowledge of French and German; that the study of mathematics is of great value in preparing the mind for the higher and deeper studies that require exact and prolonged efforts on the part of the student; that the principles of bacteriology, botany, biology, embryology, chemistry, physics and allied scientific branches are prerequisite before a student can enter intelligently upon the course in the modern medical school. The medical schools and the colleges and universities should come into more intimate relations on these propositions, and thereby insure a better preparation for the future medical students than their predecessors have had, and I believe that that condition will be brought about in the near future.

ELEMENTARY BRANCHES OF THE MEDICAL COURSE

Anatomy, physiology, chemistry and materia medica were formerly and are to-day classed as the elementary studies in a medical curriculum, but witness the subdivision of anatomy into its various normal and pathologic sections, so that its study as a basic subject is now spread over more time than was formerly allotted to the entire course in medicine. Physiology, while it has not been amplified to the same extent as anatomy, has become more intimately united with the clinical side of medicine and has carried several subdivisions of chemistry along with it. Materia medica and chemistry have remained strong and intimate allies and are still going hand in hand.

PHARMACY AND ITS RELATIONS.

Pharmacy or the science of preparing the drugs used in medicine has a chemical basis; pharmacology or the science treating of the action of drugs on the animal economy concedes the action to be due to a chemical union of some type between the drug and the cell elements; therapeutics or the application of drugs in the treatment of pathologic conditions must consider their pharmacy and pharmacology.

The value of the thorough study of these elementary branches and their subdivisions, to one intending to continue the preparation for the practice of medicine and surgery, is as self-evident as the need of a proper foundation for the erection of the modern building, they must be present and in proper position or the student is unable to complete his course, and continues throughout his professional life crippled by incomplete preparation.

Pharmacy is defined as the art or practice of preparing, compounding and dispensing medicines, and more completely by Remington which treats of medicinal substances, comprehending not only a knowledge of medicines and the art of preparing and dispensing them, but also their identification, selection, preservation, combination and analysis. Thus we can see the importance of training the medical student in a science that controls the quality of his drug remedial agents. The pharmacy student needs a more thorough course than the medical student, but the latter should be instructed in the principles of pharmacy and pharmaceutical processes so that he can intelligently order the

use of their products. Pharmacy deals with the origin or source of the drugs; the methods of extraction, purification and preparation of the finished from the crude forms; the chemical and physical properties and the preservation of the crude and finished products; the determination of the strength or the standardization of the finished preparations; and the best methods of combination so that the drugs can be administered with a minimum disturbance to the patient's system and be dissolved for absorption with a minimum delay.

The teaching of this subject in a medical school requires a combination of pharmacist and physician or one who has had a pharmacy education and practice that has subsequently been modified by a medical education and practice, thereby having the faults of the one restrained and corrected by the experience in the other. The average graduate in medicine, who has had a previous training in pharmacy, prescribes with greater ease and accuracy, therefore obtains better therapeutic results than the one without this training. This combination of pharmacist and physician is hard to obtain, yet the departmental head having this in charge should be such an one as I have indicated, and he should be given such assistance and equipment as is necessary to carry out his plans for the instruction. Many of the preparations being chemicals and many, whose chemical structure is not definitely known, having a chemical or decomposing action upon others, makes necessary a knowledge of chemical principles, especially regarding decomposition reactions, thus making chemistry one of the foundations for pharmacy. Most tests for purity, identification, properties, etc., of the drugs are chemical in character. Form, solubility, weight and other physical properties are usually discussed with the chemical.

Physiology and anatomy are related to pharmacy only so far as they may govern the combinations and the size of the dosage according as to the methods of administration. Physiological tests as to strength and purity are increasing in importance owing to the introduction of more definite physiological chemical methods and of the animal and bacterial products as medicinal agents.

Materia medica in its restricted sense is merely the listing of the preparations, giving the medicinal or official name, average adult dosage and properties of the preparations named, thus becoming a branch of pharmacy; but if taken in its older and broader meaning, it includes all of pharmacy, pharmacology and therapeutics.

Pharmacology or the study of the action of drugs upon the animal economy is dependent upon the purity and form of the pharmaceutical preparations, the size of the dose, the place and method of administration, the rate of absorption and the individual reaction of the animal used in the test. Therapeutics or the use of drugs in the treatment of disease is very dependent upon the purity, strength, form and solubility of the drug used and the method of administration.

PHARMACOPEIA.

The pharmacopeia is the list of the official medicinal preparations together with directions for their preparation and tests for their identity, strength and purity. Each country has a pharmacopeia of its own, or has adopted that of some other country as its standard, and in many countries it has been made the legal standard.

The United States Pharmacopeia is revised decennially, this being carried out by a committee appointed by a convention composed of delegates from incorporated medical and pharmaceutical colleges and societies and the

United States Army, Navy and Marine Hospital services. The eighth revision is now in progress by the committee appointed by the convention of 1900. This revision committee is composed of physicians and pharmacists, has complete charge of the collection, arrangement and publication of the pharmacopeia, continuing in existence throughout a term of ten years, during which time it is collecting material for their successors' use in the next revision. The committee is selected because of the experience and capabilities of its members, and they are continually requesting and receiving advice about the various preparations from individual members of each profession. Since the statements in the pharmacopeia are thus founded upon experience and are placed in form after due consideration by the committee, their acceptance by the members of each profession should be complete and in so far as it is possible they should confine themselves to their use. The medical schools should put more stress upon these official preparations and the text that lists them, for the better they are known by the medical graduate the better he will be able to prescribe them and he will get better results from his medication. Fewer worthless drugs or mixtures will be prescribed the nearer the prescriber restricts himself to the list of official preparations. Familiarity or exact knowledge of the armamentarium is required for the successful pursuit of any professional, business or mechanical calling. Drugs are at present a necessary adjunct to the successful treatment of many pathological conditions and therefore the better preparation the physician has in this direction, the better drugs will he prescribe, and so far as drugs are needed in the case, the better results will he obtain. There is no need of the physician knowing all the official preparations, but he must at least have knowledge of the general principles governing each class and special facts about the more important members of each class.

MORE KNOWLEDGE OF PHARMACY NEEDED.

Proper prescribing, from the pharmaceutic point of view, involves consideration of the physical and chemical changes or incompatibilities that may be present, the physiologic or therapeutic incompatibilities being outside the province of pharmacy. Thus we see that the physician must have studied and retained the general principles of chemical decomposition, the chemical composition or constituents of the materials prescribed, the factors that will increase or decrease the rate and character of decompositions that may arise, the solubility in various solvents or menstrua of the drugs used, the taste and local irritability of the components of the prescription.

The physician writes his prescription with the idea of accomplishing certain results, so far as drugs will bring that to pass, and to do this the more definite his drugs are in their composition, the greater freedom from physical and chemical changes due to the combinations ordered, the greater the palatability and solubility of the mixture without a reduction in its required effects, the better will he succeed in his endeavors. Thorough training in the principles of pharmacy will enable the physician to write prescriptions that will fulfill the above requirements, thereby increasing the probabilities of obtaining the results that drug treatment can produce.

The pharmacist or compounder of the prescription should have such knowledge of his calling as to enable him to compound it with due consideration given to the points involved in its writing. Many prescriptions give irregular or imperfect effects because of the pharmacist's

lack of special knowledge required for their compounding so that chemical or physical changes will not be brought about.

The patient expects the physician to be thoroughly competent to write and the pharmacist to compound the prescription for his use, thereby insuring him a better effect and a speedier recovery from his diseased condition. Any pharmaceutical deficiency in the drug selection by the physician, or by the pharmacist in preparing the mixture will serve to decrease its efficiency and thus the patient will not receive the beneficial results he has a right to expect. We therefore can see the importance to all concerned in having a proper pharmaceutical prescription written and compounded.

THE TEMPTATION TO USE PROPRIETARY GOODS.

The examination of any pharmacist's prescription files will soon convince a physician that there is a great deal of imperfect prescribing. Many mixtures are ordered that have such prominent chemical and physical incompatibilities that they can not be combined without so many changes occurring as to render them inert, unpalatable, irritant or in some manner incapable of producing their desired effects. Many that without having a decomposition occur are so unpalatable that they can not be readily administered or after administration be retained and absorbed, whereas a little knowledge of the principles of pharmacy would frequently have enabled the prescriber to add some menstruum that would have decreased, if not completely prevented, the irritation and thereby increased his chances of obtaining the desired effects. The various elixirs, syrups, wines, solutions, etc., of proprietary or semi-proprietary character that are on the market are daily brought to the notice of the profession and the laity by circulars, agents and in the medical and lay publications. They owe their great popularity with the public to the directions so freely given in their advertising and wrapping circulars, thereby obviating the necessity of a consultation fee for the physician. The professional user finds a preparation ready-made for administration that does not require any thought on his part about compatibility or other pharmaceutical properties nor as to their dosage; for has he not been fully supplied with advertising matter describing the careful selection of the drugs, the expert assistance employed in their combination, the therapeutic indications for their use and the size and frequency of the dosage? Not only does the unprepared prescriber find liquid mixtures ready for his use, but all kinds of solid preparations are also awaiting him. No one can deny the valuable service rendered on many occasions by some of these preparations, but the physician who places his chief dependence upon these prescribes by rule and not by reason. He uses a dosage and mixture that is based on general therapeutic indications without being able to make such changes in constituents and their proportionate dosage as the special case would indicate. The free use of this class of pharmaceuticals can, in my estimation, be laid to the ease with which they can be obtained, the less knowledge demanded in their prescribing, the slight knowledge the average prescriber has of pharmacy, and the general tendency to recover from abnormal conditions if nature is not interfered with in too many ways. Just as long as drug therapy proves of value in the treatment of disease it will be a necessary portion of the students' and physicians' course of instruction and the principles that govern the selection and pharmaceutical properties of the drugs are just as important as the knowledge of their dosage and action.

The more exact the preparations can be made the more definite will be their action and they will be more exact the nearer they conform to the official or established lines indicated by the pharmacopeia. The better the instruction given the medical student upon these principles of pharmacy and pharmaceutical practices, the better able he will be to order drugs that can be administered and that will produce the therapeutic effects desirable in the diseased condition.

The fact of so much imperfect prescribing is enough to demand a better instruction in the pure pharmacy of the drugs than has been given in the past in any medical school. The tendency to draw away from this study that is being shown in many medical institutions must be corrected or their graduates will go out less prepared to prescribe drugs than they have been in the past and until we reach the condition in which we can do without drugs, the physician must prescribe them. Prescribing for his patient has always been one of the weakest points in the young physician's preparation for the practice of his profession.

CONCLUSIONS.

1. Better preliminary preparation is required (both general and scientific) than has been the rule for medical students.
2. The study of chemistry, botany and physics should be thorough, especially along the lines of their basic principles, before a student enters upon the medical course itself.
3. The pharmaceutical bearings of chemistry, botany and physics as well as the general principles of pharmacy should be considered during the first year's work in the medical school proper.
4. The next year should present the general application of the principles and practice of pharmacy to the prescribing of drugs, and should preferably be given by a teacher qualified by both pharmaceutical and medical experiences.
5. The clinical or practical year's instruction should not pass over the pharmacy of the drug treatment with a few words, but should give full directions from the pharmaceutical as well as the pharmacologic side of the use of the drug. Whenever drug treatment is indicated it is just as essential to produce beneficial results for the patient as the ability of the physician to diagnose the pathologic condition present, and pharmacy is as essential for therapeutics as pathology for diagnosis.
6. Pharmacy is the basic study that gives the physician the most exact knowledge possible regarding the quality of his drugs, hence should be begun in his earliest student days and continued throughout his entire college course and professional life, unless he becomes an osteopath or a christian scientist.
7. Adherence to the official preparations of the pharmacopeia is desirable and more thorough instruction upon its principles will prove valuable.

THE OUTDOOR TREATMENT OF TUBERCULOSIS.*

F. E. WAXHAM, M.D.

Professor Internal Medicine, Medical Department Colorado State University.
DENVER.

Few medical men will now dispute the fact that our great remedies in the treatment of tuberculosis are pure air, rest and food. The more abundantly the former can be given the greater and faster will be the progress.

* A paper presented at the meeting of the Colorado State Medical Society at Pueblo, June 24-26, 1902.

towards recovery. Pure air in greatest abundance can best be secured by tent life. It is a pleasure to witness the rapid improvement when this mode of life is inaugurated. The sleep becomes more restful and refreshing, the appetite is improved and the vigor and vitality greatly increased.

Tent life does not mean or should not mean roughing it, as many suppose. The same watchful care should be exercised, as good food given, as comfortable a bed, as much rest, as would be obtained in the most luxurious home or the best equipped closed sanitarium. The unfortunate results arising from mistaken notions in this regard has been most forcibly emphasized by a case recently coming under my observation. A young man with rapidly developing tuberculosis, rapid emaciation, daily fever, with little appetite and little strength, was advised by his physician to come west. He was told to get a tent and a horse and rough it. He was advised to cook his own food and to take care of himself and of his horse whether he liked it or not. He graphically described his experience, and were not the results so serious they would have been amusing. He said: "I had never been on a horse but once in my life. I lifted a heavy saddle on and off several times a day, hauled away at the cinch band, fought to get the bit in, chopped bales of hay and straw, carried pails of water, etc. In consequence I had the most horribly strained right lung and shoulder on earth. The temperature went up to 104 and the pulse 118."

A tubercular patient with little appetite, with little strength, with progressive emaciation and fever, is in no condition whatever to rough it or to take care of himself. Indeed, it should now be recognized as a cardinal principle that a tubercular patient in such condition should be given rest and quiet instead of exercise, and if the temperature is high the rest should be absolute. Not infrequently people are sent from the east to a high altitude and are advised to take little or no medicine, but to depend on fresh air and exercise. The advice should be for fresh air and no exercise until the patient becomes acclimated or until the fever has subsided, if present.

The idea of tent life has so long been identified with roughing it, with hardship and inconvenience and so many physicians still cling to the thought that the strenuous life of the camper is a part of the treatment that it is often difficult to impress any other idea. The hardships and the inconvenience of tent life where one is obliged to do all the work and to care for himself is often distasteful and irksome to a perfectly well and strong individual, but to the invalid with little strength, with no appetite and with fever, such a life is positively most injurious. While advising tent life as the means of obtaining the greatest amount of pure fresh air, yet we would advise with it and as a part of the treatment, food, rest and comfort. To insure the best results those who take up tent life should do so under careful medical supervision in order that the amount of exercise, as well as the food and medication, may be regulated according to the needs and the condition of the patient.

Instead of large closed sanitarium I have long been convinced that the outdoor treatment of tuberculosis as represented by tent life, so arranged as to give every comfort, and every facility that might be obtained in the best equipped closed sanitarium would be the means of saving a far larger proportion of our tubercular patients. The best results will be obtained in that climate that will permit of sleeping in a tent the year round. We should preferably select a climate with sufficient altitude,

with dryness, uniformity of temperature, and of sufficient mildness to permit of a practically outdoor life night and day during the whole year. Many such localities can be found in New Mexico and among the foothills of Arizona. The climate of Colorado is too rigorous for an outdoor life during the winter season, but many patients sleep in tents here from the early summer until October, and some even as late as December, with the greatest benefit. The winters of Colorado are too severe for the majority of tubercular cases and the summers of New Mexico and Arizona are too hot and uncomfortable for the best welfare of these cases unless they flee from the arid plains to the mountains during this season. I am convinced that the best results are obtained by shifting these patients about, allowing them to take up their residence and outdoor life in Colorado during the summer season and permitting them to spend the winters in the same manner in Arizona or New Mexico.

A CORK NASAL SPLINT.

HAROLD WILSON, M.D.

DETROIT.

The ordinary Asch or Mayer hard rubber splint used after operations on the nasal septum is by no means a comfortable thing to wear. Its anterior lower edge projects conspicuously,

A. The splint. B. Diagrammatic section of nose, showing splint in place. Observe the angle (140 degrees), which the anterior face of splint makes with the nasal floor.

while its upper edge, by its constant pressure, generally makes the tip of the nose very tender and painful. Some metallic splints I have seen are cleverly contrived, but the patient is unpleasantly conscious of their weight, and I am not sure but they have a tendency to fall out of the nose. Cork seems to offer, by its lightness and elasticity, some decided advantages, and I have made and used some splints of this material which have proved very satisfactory. The surgeon may make them for himself, with the aid of a sharp knife, a file and some sandpaper. A hole is bored through a piece of cork of proper size by means of a perforator, and the splint is shaped to suit the needs of the individual case. After the splint is shaped, it is dropped into hot melted paraffin, which both sterilizes it and fills up the numerous inequalities in its surface, so that it does not absorb the nasal secretions and its cleansing is easy. It will be noticed by the figure that the splint, when in place, is completely within the nasal cavity. Owing to this, as well as to its color, it may be worn without being conspicuous. Moreover, its lightness makes it very comfortable for the patient, and the tip of the nose does not become sore from pressure.

32 West Adams Avenue.

COMPASSION and timidity are mistaken kindness at the first dressing of the ordinary fracture of the lower end of the radius.—Roberts.

THE INTERRELATION OF CELLS AND ORGANS.

Studies of the typical internal secretions of glands, and of the career of foodstuffs in the many changes they undergo before completing the round of metabolism, have made general the knowledge of the interdependence of the organs, and for that matter of the cells, on each other. It is because of this interdependence that a failure on the part of one group of cells often leads to changes in a remote group, the results of which may overshadow the results from the original lesions. Likewise, the "vicious circle" may be developed by the failure of one sort of metabolic change throwing an entirely different but dependent process out of action, which in turn interferes with the already abnormal process that first became disordered. Such examples of interdependence are rather obscure and indefinite to serve as illustrations of an important principle, and perhaps more simple and interesting examples are furnished in the case of secretions that are by themselves inactive and that require another secretion to render them capable of performing the functions for which they are intended. Pepsin is a case in point, and a familiar one. By itself it is perfectly inert, and will not attack proteids in the slightest degree; but combined with another secretion of the gastric mucosa, hydrochloric acid, which is as characteristic a secretion of that organ as the pepsin itself, the "pepsin-hydrochloric-acid" so formed performs the digestive functions of the stomach. Here we have to do with two secretions produced by one organ which have no function alone, but must be combined to produce the most characteristic effect of that organ. More remarkable, even, is the case of one organ forming the substance necessary for the completion of an active secretion of another organ, but this relation is undoubtedly true of the pancreas, the spleen and the intestinal mucosa.

Many years ago Schiff corroborated the observations of earlier experimenters that the extract of the pancreas of fasting animals does not have much if any power of digesting proteids, although just as capable of digesting starches and splitting fats as in feeding animals. But the extract of a pancreas removed while gastric digestion is at its height will be found possessed of a considerable degree of proteolytic power. Schiff connected this increased tryptic activity of the pancreas with the synchronous enlargement of the spleen, and by experiment soon found that splenectomy prevented the

development of tryptic activity even during digestion; the same effect was obtained by preventing the spleen from dilating as it normally does during digestion. More recently this important work has received delayed attention, and it has been corroborated in full as well as amplified. L. B. Mendel and L. F. Rettger¹ have found that while extracts of the spleen, or defibrinated blood from the splenic vein increase the proteolytic power of the pancreas, this power is lost by boiling the extract. This, of course, suggests that the active substance may be an enzyme, an idea which is supported by the observation that the alcoholic precipitate of active splenic extract contains the substance in a condition soluble in water, a behavior usual with enzymes. So it may be permissible for us to ascribe to the spleen a direct part in digestion, consisting of the production of an enzyme or similar body that converts the inactive "trypsinogen" of the pancreas into trypsin, this activating agent being discharged from the spleen during the congestion that accompanies gastric digestion.

But of how much importance is this function, interesting as it is, as a disclosure of one of the "mysteries of the spleen?" No particular digestive disturbance has been observed after splenectomy in man, and the more systematic studies in lower animals have shown that the intestinal proteolysis is undisturbed after removal of the spleen. Even in dogs, whose stomach has been isolated from the alimentary tract after splenectomy, thus leaving all of the digestion to the intestines without aid of stomach or pancreas, the digestion of meat is accomplished quite satisfactorily. How does the inert trypsinogen of the pancreas become transformed into trypsin in this case? The workers in Pawlow's laboratory in Russia, among many other valuable contributions to our knowledge of digestion of foods, have determined the presence in the intestinal juice and in extracts of the intestinal mucosa of a substance with properties that indicate that it is an enzyme, which has much the same effect on inactive fresh extracts of the pancreas as do the extracts of the spleen. This substance they have called *enterokinase*.² As a matter of fact, this intestinal energizer of the proteolytic enzyme of pancreatic juice seems to be much more active than the splenic extracts, and probably plays a more important part in normal digestion. We find, therefore, that the pancreatic trypsinogen is made active in the gland itself by substances brought to the gland in the blood from the spleen, and also that any inert trypsinogen that passes into the intestine is there activated by the enterokinase. The value of this arrangement seems to depend on the fact that the fat-splitting and starch-digesting enzymes of the pancreatic juice are destroyed very readily by the pro-

1. American Journal of Physiology, 1902, vii, 387.

2. P. Borissow presents a review of the work in Pawlow's laboratories in International Clinics, 1902, 12th series, vols. II and III, 274 and 247. An English translation, by W. H. Thompson, of Pawlow's Lectures on the Digestive Glands, has just been issued by Lippincott. It should be read by those who wish to appreciate the character of the experimental work that is being done in the study of the physiology of digestion.

teid-splitting enzyme, so that if the pancreatic juice were actively proteolytic from the start it would not accomplish much digestion of the other varieties of food-stuffs. Now the Russians have shown that on a meat diet the fresh pancreatic juice contains nearly all of its trypsin in the active form, probably made so by intrapancreatic action of the "enzyme" from the spleen; whereas, with a bread diet, in which the spleen becomes much less congested, the juice, as elaborated into the pancreatic ducts, contains much more of the inactive trypsinogen, and is correspondingly less actively proteolytic. This gives the starch-digesting and fat-splitting enzymes an opportunity to act for a while without injury by the trypsin, since it requires some little time for the enterokinase to be secreted and to convert the trypsinogen into trypsin. This complicated arrangement produces, therefore, an ideal result; an actively proteolytic fluid with proteid diet, and an actively amylolytic and lipolytic juice with a starchy or fatty diet.

Interesting and valuable as these results are, it may well be that their greatest importance is to be sought in future researches that they may incite. May it not be that many of the organs whose functions are still unknown have a very important purpose to perform in combining with the output of some other organ? Such a function could have been readily overlooked in the lack of any facts calling attention to this possibility. May not even the bothersome vermiform appendix have its own particular effect on the secretions of the rest of the alimentary canal, and be like the splenic function, valuable but not essential, and so not detected after simple appendectomy? A host of other possibilities arise to mind quickly enough, which might lead to studies of correlated action in numbers magnified by combinations and permutations toward the infinite.

SETTLEMENT WORK AND HYGIENE.

Under the name of settlement work there has come in most of our large cities in recent years an organized effort to bring at least some of the better educated classes, mostly young university men and women, into personal contact with the very poor and the ignorant in the tenement-house districts. Modern great city life, especially in this country, has brought almost absolute separation of the classes. In certain of the great cities abroad it still sometimes happens that the houses facing on the street and those on the courtyard of a square may shelter widely-separated members of the social scale, but this is practically never the case in the United States. This separation deprives the poor and ignorant of one of their most effective influences for cleanliness and hygienic living, the example of those whom they look up to and whom they respect. This is unfortunate, since example, especially in such matters, counts for so much more than precept. Any means, then, that promises to undo, even to a slight extent, the evil of present conditions should be heartily welcomed.

We have come to realize of late years that there is a much more intimate relation between the health of the poor and of the well-to-do in a large city than has been hitherto thought. The tenement can not be kept from affecting the life of the mansion. Disease is not merely the consequence of overcrowding and dirt, but it may be conveyed even to those in the best sanitary circumstances if once allowed to gain a foothold that intensifies its original virulence. Disease germs are much less frequently conveyed through the air than used to be imagined, but modes of transmission are sure not to be lacking if once favorable conditions for the multiplication of specific micro-organisms are established. There is an inevitable solidarity between the different parts of a city in the matter of health and those who are interested in humanitarian progress thoroughly appreciate this fact.

There is every reason, then, for physicians to take an active interest in settlement work, and especially to see that those who devote themselves to this social uplifting shall be properly instructed and possessed of rational ideas on questions of hygiene and sanitation. It not infrequently happens that those whose characters prompt them to such altruistic occupations are not entirely in accord with modern scientific medical notions. The anti-vivisectionists, anti-vaccinationists, and many other "antis" find in such work a favorable opportunity for the propagation of their ideas. Needless to say, they may in this way do great harm. If medical students looking for congenial occupation during vacations can be directed to this kind of work in addition to attendance at dispensaries, there is undoubtedly a great field for good. Physicians should realize the possibilities there are in this matter, now that settlement work is becoming a recognized institution of great city life. We have noted with approval that in more than one of the large cities women physicians have interested themselves in such work, and are even the heads of institutions. Male physicians are not so prominent, and it would almost seem that an opportunity for the noblest professional work, one calculated to be of supreme philanthropic importance, is being neglected.

SPLENIC ANEMIA.

The condition of enlargement of the spleen with anemia has attracted a good deal of attention within recent years. It has been given a number of different names and no doubt different affections have been described under the same name. Despite the careful study to which the disorder has been subjected there is no unanimity of opinion as to its nature and origin. Osler defines the affection as a special malady of unknown etiology, characterized by a chronic course, enlargement of the spleen, anemia of a secondary type, a marked tendency to hemorrhage from the stomach and a liability to be associated in the late stages with jaundice, cirrhosis of the liver and ascites. He considers it probable that the conditions described separately in the lit-

erature as primitive splenomegaly, splenic anemia and splenomegalic cirrhosis of the liver or Banti's disease, are stages of one and the same malady.

In a recent paper on the subject, Osler¹ reports a group of cases and gives the results of their analysis, together with that of a series of cases communicated to him by his fellow-members of the Association of American Physicians, and concluding with a summary of the clinical features of the disease. Of 15 cases under Osler's observation, 13 occurred in males and 2 in females. All were in adults, chiefly young adults; in only one had the disease begun in childhood. From the etiologic standpoint there was in five a history of malarial fever earlier in life. Heredity played no part in any of the cases, although a familial relation was noted in some cases reported by others. The peculiar characteristic of the disorder is its extraordinary chronicity, some of the cases lasting more than 12 years and the duration in two of the reported cases being 25 years.

The special feature of the enlarged spleen of chronic splenic anemia is its great size—being greater than in any other disease, with the exception, perhaps, of leukemia. Hematemesis is a remarkable symptom of the disorder, being present in a considerable percentage of the cases and attaining large proportions at times. It may continue throughout many years, and it is believed to be due in a large number of cases to conditions associated with enlargement of the spleen. Hemorrhage from other sources is much less frequent. Epistaxis may recur at intervals; retinal hemorrhages, bleeding from the gums, menorrhagia and hematuria have been recorded, and purpuric attacks may occur. The state of the blood is peculiar, there being but a slight diminution in the number of red corpuscles, with a low percentage of hemoglobin and also a small number of leucocytes. Pigmentation of the skin is common in cases of long standing, often assuming a diffuse bronzing, although at times it appears as a steel-gray staining, while in some it has been patchy and associated with areas of leukoderma. In most cases there are no symptoms referable to the liver; in a few ascites is present; while in others symptoms suggestive of cirrhosis of the liver dominate the clinical picture. Jaundice has been observed occasionally. Often the liver is normal in size; at times it is enlarged; rarely it is diminished in size. The morbid anatomy of the affection comprises a fibrosis and hyperplasia with atrophy of the splenic pulp and a hyaline degeneration of the Malpighian bodies; and also displacement of the normal texture by fibrous tissue and large endothelial cells with clear protoplasm containing two or more nuclei, and among them giant cells.

The disorder appears to be dependent on a chronic toxic rather than an infective process, but the character and the source of the poison are as yet undiscovered. The only known successful treatment consists in removal of the enlarged spleen.

WELTMERISM AGAIN.

Some time ago the Postmaster General excluded the Weltmer magnetic healing concern of Nevada, Missouri, from postal privileges and an appeal to the courts sustained the order. The United States Supreme Court has now overruled the decision of the lower tribunals, thus restoring to the pretenders the use of the mails. According to the press reports, which are all we have at present, the decision makes a general ruling as regards the rights of medical healing pretenders to the use of the mails. It says, as reported, in effect that however extravagant the claims that are made no one can set the limit where the statutes are violated. "There is no exact standard of absolute truth by which to prove the assertion false and a fraud."

This seems to us rather a broad statement, for there must be some difference between the truth and a lie. As we recollect it, this Weltmer concern not only claimed to cure by correspondence, but also had a pretended system of aiding its dupes in money-getting by absent treatment or influence, or something of that sort. The postal authorities were convinced of the fraudulent nature of the business by the absolute lack of correspondence between Weltmer's claims and the amount of business done. It was an absolute impossibility for a man to give any individual attention to the cases represented in his correspondence, which kept some eighty typewriters busy, without any relation whatever to the question of the truth or falsity of so-called magnetic healing. The case was not improved for him by the alleged fact that while his typewriters were copying off the forms to send to his dupes he was refreshing himself in Colorado and could have no knowledge of even the names of the 25,000 or more whose communications with him were stopped. We do not know how the case was presented to the court, and it may be that this aspect was not made very prominent, but if it was the decision and remarks on magnetic healing and its possible validity seem to be rather gratuitous.

We would ordinarily hesitate in criticising a decision of the Supreme Court, but this one appears to us to be a judicial blunder. Judges and other laymen often give out queer opinions on medical matters, but good business sense ought to be enough to make clear the fraudulency of such a pretender as Weltmer. The opinion, however, does not seem to be final as to all points, and it may be only a temporary victory for the concern, but what is published of this extraordinary decision does not commend itself, even to the editors of the leading lay journals of the country as we see by their editorial comments on the case.

A NEW FIELD FOR EDDYISM.

Weltmer does not seem to be the only one who claims power to make rich as well as to heal. We read of a certain Prof. William Windsor of the "International College of Science" of Boston, who goes around lectur-

1. American Journal of the Medical Sciences, November, 1902, p. 751.

ing on "vitosophy," a science that not only can cure all diseases except those which require surgical aid, but will also make those who master it rich and happy. Eddyism and Dowieism will have now to add worldly wealth to their other inducements or they will be behind the times. "How to make one rich" would be a very good text for either Dowie or Mrs. Eddy—they can speak from experience—but how about the many?

MILK AND PUBLIC HEALTH.

The subject of milk in its relations to public health is very thoroughly discussed in a recent report by Dr. George M. Kober and published as Senate Document No. 441. The larger part of the work is taken up by the various appendices, which give the composition of normal milk and its legitimate variations, its adulteration with preservatives, etc., the methods of milk inspection and examination, chemical and bacteriologic; the details of sanitary dairy management and other matters that are of interest in regard to this most important food product. There is also an exhaustive bibliography. The subject of abnormal milk is fully treated, including a discussion of the living question of the day—the transmission of bovine tuberculosis by milk. The author still considers this question to some degree an open one, requiring further and careful investigation before we can speak positively as to the full extent of the danger from this source. He agrees, however, that there is already sufficient evidence to warrant all reasonable precautions. The document concludes with a tabulated statement of disease epidemics, typhoid, scarlatina and diphtheria, that have been credited to the milk supply, and a good index. It is the most convenient and complete monograph of its subject that we have yet seen and deserves a wide circulation. We are not sure how generally accessible it is or will be to the general public as a government document, and its republication, with such additions and revision as the studies of the subject may make necessary, might be advisable.

THE SCIENTIFIC EXHIBIT.

We print this week¹ the report of the Committee on Pathologic Exhibit at the Saratoga meeting. This exhibit has now been a feature of the annual sessions of the American Medical Association for three successive years and has attracted a great deal of attention. Being in the beginning stage it naturally has been open to some criticism. That it has lacked definiteness of purpose, and that the best possible use of the material has not been had, is not to be wondered at. Now the scope of the exhibit has been broadened, as is shown by the change of title from Pathologic Exhibit to Scientific Exhibit, and at the last session of the House of Delegates arranged for co-operation on the part of the sections with the committee arranging the exhibit. Would not the value of the exhibit be materially increased if the secretaries of the sections could secure for the exhibit all specimens that are to be used, or that could be used, for the illustration of the papers that are to be read in their sections? Furthermore, would it not add

to the general interest if specimens illustrating present or past research could be shown in considerable numbers in this exhibit? Last year the Section on Ophthalmology had a display of ophthalmoscopes, showing the various steps in the evolution of this instrument. No better place for such a display could be conceived than this exhibit. Would it not be a good idea to institute demonstrations of specimens by men who are especially capable of conducting such demonstrations? For example, suppose that during each afternoon certain men be selected to talk on the specimens that they might care to demonstrate. Thus, the Section on Ophthalmology might ask some scientist to talk on the eye specimens that are on exhibit. That on Dermatology might ask for a similar demonstration by some distinguished skin specialist. This plan would, on the one hand, materially increase the usefulness of the exhibit, while, on the other, it would tend to secure a high grade of specimens.

THE PLAGUE IN CALIFORNIA.

A certain portion of the California press is still raving and maintaining that there is and has been no bubonic plague in that state; this, too, in spite of the convincing evidence that seems at last to have silenced the sole local medical journal hitherto advocating their views. They do not appear to be aware that the country generally does not accept the testimony of such sanitary experts as Governor Gage, Mayor Schmitz and bacteriologist Mouser against that of all other authorities in the country and the almost unanimous opinion expressed by the California State Medical Society. If this course is kept up we will probably see some states quarantining again California—indeed, that is already threatened. The country does not fear the plague so much as long as it knows that the city health authorities of San Francisco are still in power and are permitted to do their duty. But this is not a full assurance of safety so long as it is certain that the state authorities will not co-operate but will continue their policy of the past, denying the existence of the pest and doing nothing to curb it. There is no certainty that it does not exist unrecognized elsewhere in the state in places where there are no adequate health regulations or sanitary officials. The Chinese are numerous throughout California and are very secretive in such matters. Their success in hiding plague cases was shown in Hong Kong, where, in spite of all official vigilance, they were often only revealed after death when the bodies were thrown into the streets. What may happen in remote Chinese settlements on the Pacific coast no one knows. Our hopes rest on the incoming administration, which we feel assured will not follow the example of its predecessor. With state and city authorities of the coast alike alive to the needs of the situation, the rest of the country will feel grateful relief from the unpleasant suspense that now exists. While *THE JOURNAL* has discontinued its special detailed reports of plague cases for some time, they have continued to occur latterly at the rate of at least eight or ten a month, and seem to be increasing. In the meantime the attitude of some of the citizens and

1. See page 1404.

officials is more interesting psychologically than it is satisfactory in other respects. It is not pleasant to think of bubonic plague becoming endemic, even if it does not become epidemic in this country.

Medical News.

COLORADO.

Personal.—Dr. W. C. Foster, Pueblo, as the result of a competitive examination, has been appointed city physician of Manila, P. I.

Without License.—"Dr." J. C. Maroney, Denver, was tried, November 18, on the charge of practicing medicine without a license. He was found guilty and sentenced to pay a fine of \$200 and to ten days' imprisonment in the county jail. The jail sentence was waived on payment of the fine.

New Home for Consumptives.—The Mrs. Charles L. Adams Memorial Home, Denver, built at a cost of \$50,000 by Mr. Charles Adams of New York, in memory of his wife, and intended for consumptives of limited means, was dedicated, November 26, with appropriate ceremonies, by Bishop Olmsted of Colorado. The institution has accommodation for forty patients.

Death and Disease in October.—During the month 802 deaths and 27 stillbirths were reported, an annual death rate of 16.26 per 1000. Diphtheria caused 18 deaths, scarlet fever 4, smallpox 1, and typhoid fever 83. The cases of diphtheria reported numbered 107, of scarlet fever 112, of smallpox 25, and of typhoid fever 655. Compared with the previous month the reports show an increase of 38 cases of diphtheria, 52 cases of scarlet fever, 3 cases of smallpox and 13 cases of typhoid fever.

An Ethical Question.—At the bi-monthly meeting of the Pueblo County Medical Society, held November 18, questions of professional ethics were discussed, and the action of Dr. Richard W. Corwin in allowing his picture to appear in the daily papers in connection with his recent performance of the Lorenz operation for the cure of congenital hip dislocation was given consideration. The local newspapers say that while no resolution was passed on the subject members of the society, with some exceptions, expressed their disapproval of this sort of publicity.

ILLINOIS.

Expectoration Prohibited on Sidewalks.—A resolution was passed by the Springfield Board of Health, November 11, prohibiting expectoration on sidewalks and in public places.

Hospital Fireproof.—The new Rockford Hospital is to be made fireproof, and in connection with the hospital a nurses' home will be erected. The total cost of the building will be \$53,000.

St. Charles Hospital Open.—The new St. Charles Hospital was dedicated by Bishop Muldoon, November 25. It was founded by the Franciscan Sisters of Joliet and represents an outlay of \$50,000. It will soon be ready to receive patients.

Neely Appointed.—President Hanberg of the county board, on November 24, appointed Dr. John R. Neely superintendent of the county institutions at Dunning. The appointment is to take effect at once. Dr. Neely has been medical director of the institution for some time.

Personal.—Dr. Harry R. Lemen, Upper Alton, has returned home after three years in the United States service in the Philippine Islands.—Drs. M. D. Empson, Hartford, and James W. Armstrong, Centralia, were elected vice-presidents of the Southern Illinois Medical Association at its recent meeting.

Public Advertisement Undesirable.—A committee of physicians representing the Quincy and Adams county medical societies, called on the newspapers of Quincy, November 18, and requested them not to publish the names of physicians connected with cases which from day to day come up, and in which the public is interested.

Chicago.

Personal.—Dr. and Mrs. G. Frank Lydston have returned from the Orient.

Degree for Dr. Lorenz.—On November 28, Northwestern University conferred the degree of LL.D. on Dr. Adolf Lorenz of Vienna.

Will Protect Its Members.—The Chicago Medical Society, acting on the recommendation of a committee, has decided that hereafter all suits for malpractice brought against its members

will be contested by counsel provided by the society. Under the proposed plan a medicolegal committee and a medicolegal fund will be established.

Importance of Diagnosis in Diphtheria.—From the Bulletin of the Chicago Health Department for the week ending November 22 we quote the following:

Investigations of the deaths from diphtheria show that many of them were due to a deceptive type of the disease. Parents and some physicians even have been deceived when the most malignant form of the disease was present and death has ensued because the administration of antitoxin was thereby delayed. All persons having the care of children should keep in mind that the disease may be in the back part of the nose or in the windpipe, as well as in the throat, where the membrane can be seen. There may be little or no pain or fever and on the second day the child may seem better. The poison of the disease often causes dulness and stupor. Hoarseness and difficult breathing indicate diphtheria of the windpipe. The true nature of the disease can only be learned by taking a culture, and, when there are so many of these cases present as now, this should never be omitted. Antitoxin should be administered at once in every suspicious throat case; it can do no possible harm in any event; it will certainly prevent death from diphtheria if used within the first forty-eight hours.

The laboratory examinations show some decrease in the presence of the diphtheria bacillus; it was found in less than 50 per cent. of the cultures examined. The week before it was present in more than 60 per cent. of the cultures, but it was found more frequently last week in cases not suspected to be diphtheria.

SMALLPOX.

There were six cases of smallpox admitted to the isolation hospital during the week—two from Evanston direct, three children attending a parochial school in Evanston but living near the northern city limits, and a travelling man who contracted the disease probably in Milwaukee. None of these had ever been vaccinated. At the close of the week there were 11 cases remaining in the isolation hospital, 7 having been discharged recovered, and no deaths.

LOW NOVEMBER MORTALITY.

Notwithstanding the threatening indications of a high death-rate during the early part of the month, November bids fair to maintain its position of lowest monthly death-rate of the year. The 1,437 deaths reported during the first twenty-two days represent an annual rate of 13.09 per 1,000 of population. This is nearly 20 per cent. less than the average November rate during the decade 1881-1890, and 9.1 per cent. less than the average November rate during the decade 1891-1900.

INDIANA.

Deaths From Violence.—Of the 2559 deaths in Indiana in October, 146, or about 5 per cent., were due to violence. Rail road and street car accidents caused the deaths of 32 persons, of whom 26 were males and 6 females. Of the 146, 118 were accidental and 26 were suicides, of which 21 were males and 5 females. There were 8 murders, 7 were accidentally poisoned, and 7 drowned, 4 killed by machinery, 17 by burns and scalds, and 11 died of gunshot wounds. Five persons died of strangulation from food. Six persons chose hanging, 7 shooting, 3 carbolic acid, 2 morphin, and 2 arsenic as a means of committing suicide, and paris green, rat poison, strangulation and prussic acid each killed one.

MASSACHUSETTS.

Endows Chair of Comparative Anatomy.—James Stillman, president of the National City Bank, New York, has presented \$100,000 to Harvard University for the endowment of a professorship in comparative anatomy.

Practicing Without License.—William L. Williamson, Taunton, who claims that he has been practicing in that city for ten years, and that he has been in practice for more than thirty years, has been brought before the District Court charged with practicing medicine without being qualified under the Massachusetts law. The name of this individual is not to be found in the medical directories.

Harvard Tuition Fees Advanced.—The corporation of the Harvard Medical School has approved the vote of the faculty to raise the tuition for the fourth year from \$100 to \$200, making the fees uniform through the four years. When only three years were required for a degree, the fourth year tuition was made less to encourage students to take it, but now that the requirements are for four years of study, the change is made in the interests of uniformity.

NEW YORK.

Personal.—Dr. John F. Fitz Gerald, superintendent of the Rome State Custodial Asylum, has resigned to accept the position of general medical superintendent of the Kings County General Hospitals, four in number, in Brooklyn.—Dr. John D. Curran of the staff of the Binghamton State Hospital, has resigned, and will go into private practice.

Status of Medical Examiners Decided.—By a ruling of the State Civil Service Commission, the positions of county medical examiner and assistant medical examiner are exempt from the civil service law. The salaries due to Medical Examiners

Danser and Assistant Medical Examiner Howland of Erie County, which have been held back awaiting the decision, have accordingly paid them from the date of their appointment.

Smallpox Emergency Fund.—The Board of Estimate and Apportionment of Rochester has adopted resolutions appropriating another smallpox emergency fund of \$25,000. The \$50,000 fund appropriated some time ago is exhausted. Of the new fund about \$10,000 is to be applied to building the new hospital and the remainder is to be used for the care of smallpox patients. It is expected that the additional appropriation will be sufficient at least for the remainder of the year.

New York City.

Physician Assaulted.—Dr. Simon Glug, while on his way home at 3 o'clock in the morning, was assaulted by three men, one of whom was captured and identified.

Generous Gift to Hebrew Charity.—The six daughters of the late Leonard Lewisoohn have donated to the Hebrew Sheltering Guardian Society the sum of \$125,000, \$50,000 being given outright, and the balance on the condition that the society shall secure a similar amount to complete the building fund within a year. The entire amount needed is \$400,000, of which \$110,000 have been already subscribed.

The New French Hospital.—The ceremony of laying the cornerstone of the new French Hospital took place, November 18, in the presence of many distinguished persons, including the French ambassador, M. Jules Cambon. The new edifice is to be erected a little west of the present site of the hospital. The new building will have 150 ward beds and some private rooms, and while intended principally for French people, the hospital is non-sectarian and all nationalities will be admitted.

Throat Department Closed.—The directors of this institution have finally decided to close the throat department of the New York Eye and Ear Infirmary, which has been in existence for 28 years. Last year alone it treated 9600 new patients. A limited number of the old throat patients will continue to receive treatment, but retrenchment has been found necessary because, it is said, of the enormous crowds of school children brought daily to the infirmary for the treatment of trachoma. To offset the unpleasant rumors that have been abroad regarding disagreements with the physicians in the throat department, the directors reappointed the whole staff for another year.

Preparing for the Lorenz Visit.—Up to date, several hundred applications for treatment by Dr. Lorenz have been recorded at the Cornell Medical College and at the Hospital for Ruptured and Crippled, and to facilitate the work of selection a large number of the cases have been examined with the x-ray. Incidentally this excitement among the deformed persons in the community has been the means of bringing to light a surprisingly large number of cripples, and this has led Dr. Newton M. Shaffer, and others, to start a movement to ask the next legislature to appropriate \$100,000 for a new and more capacious hospital for the care of such children. The present state hospital for this purpose is situated at Tarrytown, and accommodates only 25 patients. Dr. Lorenz is expected to reach this city December 6.

An Unlicensed Drug Clerk.—An unlicensed junior clerk in a drug store on Ninth Avenue recently sold a mixture of castor oil and almond oil to some children. They returned shortly afterward, complaining that their grandmother said the medicine was not right, as she could smell no almond oil in it. The clerk said he would fix it, and evidently did so by adding a liberal quantity of oil of bitter almond, for shortly afterward the grandmother and one child were dead from cyanid poisoning. The proprietor of the store, when asked by the coroner why he allowed so inexperienced a clerk to handle poisons, replied as follows: "He was not allowed to fill prescriptions. A mixture of castor oil and almond oil is not a prescription. He had as much right to sell it as he had to sell patent medicine."

Opposition to Coroners.—At the last meeting of the New York County Medical Association, a resolution was introduced by Dr. Harry R. Purdy, and unanimously adopted, directing the appointment of a committee to investigate the question of abolishing the archaic office of coroner. The committee appointed consists of Dr. Stephen Smith, chairman, with Drs. E. Eliot Harris and Harry R. Purdy as his associates. This committee will co-operate with the committee on legislation of the state association, and it is probable that the county medical society will appoint a similar committee. It is the intention to introduce into the next legislature a bill abolishing the office of coroner in New York City, giving the medical part of the work to some officer chosen by the president of the board of

health, while the judicial part of the work of the coroner's office will fall on the judges and magistrates. The plan is similar to that which has been in successful operation for several years in Massachusetts.

Buffalo.

Inspection of Immigrants.—Dr. E. D. Bingham has been appointed medical inspector of the port of Niagara. The United States is evidently determined that no diseased immigrants shall enter the country. Eight immigrants were sent back yesterday. Trachoma is the principal disease brought into the United States by the immigrants, most of the sufferers being Italians.

Recommendations Anent County Hospital.—Eben P. Dorr, inspector for the State Board of Charities, has made the following recommendations concerning the Erie County Hospital of Buffalo: Exclusive and modern ambulance service; new nurses' home and conversion of the present house into a venereal ward; cottage for nursery purposes (children should be removed from the main hospital); elevator for hospital; sterilizing equipment for hospital; large ventilating shafts into hospital water closets; shower baths for women; better equipped hospital operating room; watchman's time detector; wall racks or reels for firehose; more oms for inmates of hospital, and more for medical superintendent and family.

PENNSYLVANIA.

Typhoid Fever in Reading.—There are several hundred cases of typhoid fever in Reading. Supplying pure water by the gallon to householders is said to be quite an industry. The hospitals report a scarcity of nurses.

Cornerstone Laid.—The cornerstone of the new Lancaster General Hospital was laid on November 23, with masonic ceremonies. The new building is to cost \$60,000. The institution is nine years old, and treated 403 patients last year. An annual appropriation of \$5000 toward its support is received from the state.

The State Board of Public Charities was recently in session for several days in Philadelphia considering the requests from the hospitals of the eastern section of the state for state aid. At a meeting soon to be held in Harrisburg, requests from hospitals of the western section of the state will be heard. The board makes its recommendations to the legislature next January.

The State Board of Health met in Harrisburg, November 20. The annual report of Dr. Benjamin Lee, secretary, showed that smallpox exists in 87 cities, towns and villages of the state, and that the increase in the number of cases since August 1 has exceeded 50 per cent. monthly. Most of the cases are in the western and southern sections. Dr. J. H. McClelland of Pittsburg was reappointed chairman of the legislative committee of the board, with instructions to make every effort to secure an appropriation of \$50,000 by the next legislature as an emergency fund, to be used by the board as needed to fight contagious diseases. Such a provision formerly existed, but for the past two years the legislature has failed to make an appropriation. Consequently, the board was almost helpless to respond to the appeals for aid in the smallpox epidemic of last winter. Facing the possibility of an epidemic this winter, the board urges the necessity and economy of such an appropriation. Dr. Samuel T. Davis, Lancaster, president of the board, was elected delegate to the American Public Health Association.

TENNESSEE.

Personal.—Dr. James A. Albright, Nashville, was re-elected secretary and executive officer of the Tennessee State Board of Health, at the meeting of that body, October 7.—Dr. Edgar L. Gleaves, Gallatin, health officer of Sumner County, has resigned, and will locate in Olinda.—Dr. Alfred S. Horsley, Knoxville, has been appointed surgeon-in-chief of the McDonald camp in Guatemala.—Dr. William S. De Golia succeeds Dr. Leopold H. Schwerin as surgeon for the Tennessee Central Railway, with headquarters at Crossville.—Dr. Hampton L. Fancher, Isoline, has moved to Orme.

Hospital Staff Appointed.—The newly-appointed staff of St. Thomas' Hospital, Nashville, is as follows: Drs. Charles Brower, Adam G. Nichol, S. McPheeters Glasgow, Richard A. Barr, Worcester A. Bryan, John R. Buist, Lucius E. Burch, John A. Gaines, Perry Bromberg, W. Frank Glenn, James W. Handly, James Brew, William E. Buist, Lynn B. Graddy, Marvin M. Cullom, George H. Price, Hilliard Wood, Edwin G. Wood, John A. Witherspoon, William Bailey, Robert O. Tucker,

Sidney S. Crockett, John T. Altman, James M. Coyle, Owen H. Wilson, Matthew G. Buckner, Samuel M. Bloomstein, Thomas Weaver, A. B. Cooke, Larkin Smith, Louis Leroy and James M. King.

Medical Schools Open.—The medical department of the University of Nashville opened October 1. Dr. William G. Ewing, dean, delivered the opening address. The freshman class numbered 125.—The medical department of Vanderbilt University, Nashville, opened, October 1, with addresses by Rev. W. M. Anderson, Chancellor Kirkland, and the dean, Dr. William L. Dudley.—The twenty-sixth year of the medical department of the University of Tennessee, Nashville, opened, October 1, with an address by Dr. J. Bunyon Stephens, one of the founders. Dr. Paul F. Eve presided.—Memphis Hospital Medical College began its fall session, November 3, in its new building with an enrolment of more than 700.—Chattanooga Medical College opened, October 7, with an enrolment of about 150 students.

UTAH.

Personal.—Dr. George T. Odell, Salt Lake City, has been appointed assistant physician of Salt Lake County.

Fire in Hospital.—On November 11, fire broke out in the Ogden General Hospital, but the damage to the building was not extensive.

Resolutions Regarding Dr. Verbryck.—The Salt Lake County Medical Association has passed resolutions of condolence regarding the death of Dr. George G. Verbryck.

Hypnotic Doctor Fined.—In the case of C. W. Pearce, Ogden, who claimed to be able to cure cancer and other ailments by hypnotism, the accused pleaded guilty and was fined one dollar and given time to get out of the state.

Smallpox Epidemic Feared.—There have been more than one hundred cases of smallpox in and around American Fork, about 10 per cent. of which were severe. Quarantine has been established, but it is claimed that the authorities have been unable to enforce it strictly. It is feared that the disease will be spread over the state.

VIRGINIA.

Medical College Attendance.—The enrolment at the Medical College of Virginia, Richmond, thus far is 250, and that of the University College of Medicine, in the same city, 274.

Personal.—Dr. Lemuel C. Shepard has succeeded Dr. J. Jett McCormick as city bacteriologist of Norfolk.—Dr. John W. Brown, Hampton, recently underwent an operation for appendicitis.

Richmond Hospital for Colored People.—A new corporation, to be known as the Richmond Hospital Association, has been organized, with the following officers: Dr. Richard F. Tancil, president; Dr. Harrison L. Harris, vice-president; Dr. Oswald B. H. Bowser, secretary, and Dr. John Meriweather, treasurer. It is the purpose of the incorporators to erect a large hospital in the suburbs of Richmond for the use of colored patients.

WASHINGTON.

Personal.—Dr. H. P. Miller, Fremont, was recently crushed between a fence and an electric car, and sustained a fracture of the leg.—Dr. Howard R. Keylor, Walla Walla, has been appointed physician at the state penitentiary, vice Dr. James F. Cropp.

Deaths in Washington.—In October there were recorded 406 deaths in the state, of which 246 were males and 160 females. Kings County had 102 deaths, Pierce County 49, and Spokane County 32. Accident caused 53 deaths, homicide 5, and suicide 11.

Nuisances and Communicable Diseases.—The Spokane County Board of Health has published two excellent pamphlets, one detailing the rules and law governing nuisances and their abatement, and the other, rules governing and means to prevent the spread of communicable diseases.

WISCONSIN.

Leper Dies.—Thomas Nelson, the only leper in Dane County, who had been afflicted with the disease for more than thirty years, died in his cottage at the county poor farm, November 1.

Malpractice Suits.—Frank Koeppl has asked damages of \$10,546 against Dr. Walter J. Kelly, for injuries alleged to have been received through the malpractice of the defendant.—Dr. E. Wells Kellogg, Milwaukee, has been sued for damages to the extent of \$10,000, for injuries claimed to have been received at the hands of the defendant while under treatment for a swollen wrist.

Personal.—Dr. Hoyt E. Dearholt, Milwaukee, has returned from Europe.—Dr. Oscar Chrysler will succeed Dr. Almon Clarke as surgeon at the Soldiers' Home near Milwaukee, December 31.—Dr. Charles M. Gould, West Superior, has moved to Tucson, Ariz.—Dr. William F. Beutler has returned from his trip abroad.—Dr. Alfred L. Kastner has been appointed assistant surgeon at the Soldiers' Home, vice Dr. A. Kreutzer, resigned.—Dr. Otto Braun, Merrill, has gone abroad for six months of study.—Dr. Arthur T. Holbrook, Milwaukee, has returned from a six months' course of study in Vienna.—Dr. W. I. Griffin, Ashland, has been appointed physician to the La Pointe Indian Agency, vice Dr. E. S. Davidson, deceased.—Dr. John F. Brown, Mazomanie, has been appointed physician to the state penitentiary, vice Dr. Eugene A. Smith, Waupun, resigned.

GENERAL.

A Santa Fe hospital for the Pacific Coast will be built in Los Angeles or San Bernardino, to care for the employes of the Santa Fe Railway.

A recrudescence of cholera is embarrassing the Philippine Commission and the War Department. The water supply of Manila is threatened. The outbreak in Mindinao, however, is not so severe as was at first reported.

Army Surgeon-General's Report.—In the report of the Surgeon-General of the Army for the year ending June 30, on page 45, the death rate from all causes for the year 1901 is incorrectly given as 19.94 per thousand. It should read 13.94 per thousand. The figures are correctly given in Table 1, page 148. The Surgeon-General requests that we make this announcement, as many copies of the report have been issued.

States Want California Plague Conference.—Five state boards of health have adopted a resolution calling on Surgeon-General Wyman of the United States Marine-Hospital and Public Health Service, to assemble a conference of all state health officers to take action toward the prevention of the spread of bubonic plague, known to be in San Francisco. They base their request on the dangerous policy of the California authorities.

Invalids Must Have Certificates.—The passenger agents of the Terminal Lines Association voted unanimously at the meeting at Denver, November 11, for a law requiring every invalid passenger to have a certificate from his physician stating what disease he has before boarding trains. The secretary of the association was instructed to confer with the city, county and state health officials in regard to the form of certificate best adapted for the purpose, and as soon as this is done plans will be laid for putting the new agreement into effect.

Increase in Suicide.—U. S. census reports show, according to an article in the *Spectator*, an insurance publication, an increase in the number of suicides throughout the Union. In fifty of the largest cities the average number of suicides in 1890 was 12 per 100,000 of population; in 1901 it was 16. In the intervening period at no time did the rate fall below 12, and in 1897 and 1898 it rose to 17.73. There is a wide difference in the suicide rates of some of the fifty cities. In San Francisco it was over 49 last year. Taking the average for the entire decade, the rate in St. Louis was 25.7; in Chicago, 23.3; in Hoboken, N. J., 23, and in that part of New York City included in the boroughs of Manhattan and the Bronx, 20.9; while in Trenton the rate was only 5.1, and in Fall River, Mass., 2.9.

Health of Miners Investigated.—The Strike Commission in session at Scranton summoned several physicians to testify as to the health of the miners. Testimony was to the effect that 99 per cent. of mine workers are anemic, and their general condition below par. The ills suffered especially by miners were said to be catarrh, stomach affection, pleurisy, gout, neuralgia, sciatica, lumbago, rheumatism, pneumonia and asthma. Affections of the respiratory tract were believed to result from the inhalation of coal dust, powder smoke and otherwise vitiated air. It was stated that 90 per cent. of those who reach 50 years of age are afflicted with some form of rheumatism; that few live beyond 50 years of age, the average life of a miner being 25 or 30 years. A member of the Central Poor Board of Luzerne County testified that 70 per cent. in one of the almshouses are miners, and that 40 per cent. of these are crippled by accidents at the mines.

CANADA.

Vancouver Hospital Fund.—A gift of \$1000, among other contributions, raises the Vancouver General Hospital fund to \$14,000.

Appointment.—Dr. Fiset of Quebec has been appointed staff adjutant of the Army Medical Corps of Canada. His office will be at Ottawa.

Smallpox Outbreak.—Fifty cases of smallpox are reported in Kent County, New Brunswick. For some time the affected ones concealed the fact of the outbreak, which allowed its extended spread.

The Academic Palms for Brochu of Quebec.—The French government has decorated Dr. D. Brochu, professor of internal medicine at Laval University and editor-in-chief of the *Bulletin Méd. de Québec*.

Montréal General Hospital Report.—The quarterly meeting of the Board of Governors of the Montréal General Hospital was held last week. A very interesting report was presented. The hospital seems to be in great financial stress. An anonymous subscription has recently been given to the endowment fund of \$3,000, which brings that fund up to \$43,500. The report of the medical superintendent showed 743 patients admitted to the wards in the quarter and 3,301 outdoor patients, against 720 inmates and 7,638 outdoor patients for the same quarter in 1901.

Scarlet Fever in Montréal.—The question of the erection of a new contagious diseases hospital for Montréal is again agitating the minds of the people of that city, and the urgent need has been brought forcibly home to them during the past week when the medical health officer reported that the little shack now used as a hospital for infectious diseases contained eighteen patients suffering from scarlet fever. During the past few days the disease seems to be spreading rapidly and new cases are being reported daily. The disease is said to be of a very violent type. There are only 26 beds in the temporary hospital for scarlet fever patients, and the question is what is to be done when the other beds are occupied.

Ontario Asylums.—The Hon. J. R. Stratton, the provincial secretary in the Ontario government under whose department are the asylums of the province, is quoted as alleging that within the past few months five persons were committed to the asylum as insane, the usual certificates being signed by two medical men in each case, and that all these have been returned to their homes, having been declared perfectly sane by the asylum physicians. This casts a reflection on at least ten physicians of the province, and their cases have been taken in hand by Dr. McKinnon of Guelph, a past president of the Ontario Medical Association, whose presidential address before that body two years ago entered largely into the discussion of asylum affairs in this province. It is charged by the provincial secretary that certain parties have been imposing on the province, and that there is good reason to believe that these five persons were sent to the asylum only to relieve their friends or the House of Refuge. Dr. McKinnon points out, if this be true, it is clearly the duty of the provincial secretary to lay information before the discipline committee of the Ontario Medical Council, so that an immediate investigation can be made. Dr. McKinnon then enquires what tribunal decided that these five persons were not insane, how long they were under observation, further stating that it will be interesting to follow up their future lives. Appointments in the Ontario asylum service are said to be almost wholly on political lines, a doctor-politician very often proceeding directly from the hustings or from the party caucus to the responsible position of medical superintendent of an asylum, the claims of the men who have spent their lives as asylum internes being altogether disregarded. The incident may be the means of directing attention to these anomalous appointments.

FOREIGN.

Nobel Prize.—Major Ronald Ross, Liverpool, of mosquito expedition fame, has been suggested as a probable recipient of the Nobel prize of \$15,000 for malaria research.

Greek Neurologic Periodical.—Vlavianos of Athens has founded a periodical to be devoted exclusively to subjects connected with psychiatry and neurology. The young editor has already won a name by his previous contributions to the literature of these branches.

The Italian Congress of Internal Medicine was held at Rome, October 28, with Dr. Bacelli, the president, in the chair. The main addresses were on "Intravenous Medication," by Patella and Mariani; "Hysterical Fever," by Ughetti, and the "Pathology of Nephritis," by Ascoli.

Institute for Public Hygiene.—Moscow is planning an institute to train physicians for the official sanitary service. The course will include lectures and practical demonstrations. The idea owes its origin to Professor Kapustin of Kasan, and a committee is now at work on the project.

Cholera Spreads in Holy Land.—The source of the widespread epidemic of cholera throughout Palestine, which we have mentioned, was the exodus of panic-stricken fugitives from Egypt endeavoring to escape from the visitation of cholera, which recently swept the valley of the Nile down to Cairo. The crowds escaped through the desert practically by the same route taken by the children of Israel in the exodus under Moses. They reached the Holy Land about October 10, and have spread the disease throughout the country. The lethargic government has been wholly unable to cope with the situation or to restrain the people. The ancient city of Gaza, memorable from the exploits of Samson, suffered severely, 984 deaths being recorded. The epidemic is now decreasing in all the localities first attacked, but fresh cases appear daily in new places. The total number of deaths is stated as 1864. The government is endeavoring to confine the epidemic to Palestine.

Book Notices.

LEDGER OF MONTHLY BALANCES AND INDEX OF ACCOUNTS, to Be Used in Connection with the Physicians' Protective Visiting List Constituting the Physicians' Protective Accountant. In Two Books. Leather. Price, \$2.00. Chicago: The Clinic Publishing Co. 1901.

This is a very compact, simple and economic system of keeping accounts. At first examination the general arrangement seems complicated, but this is more apparent than real, and its practical utility is soon evident when closely studied or when put into use. The system consists of two books, a ledger and a monthly visiting list. While the former is intended for the pocket it really takes the place of the ordinary ledger, and is not necessarily to be carried on one's person. The visiting list consists of a durable cover, for the monthly lists the latter being changed each month. This arrangement makes the book to be carried in the pocket, compact, light and flexible.

A TEXT-BOOK OF PATHOLOGY AND PATHOLOGIC ANATOMY. By Dr. Hans Schmar. . . . and First Assistant in the . . . ated from the Sixth German . . . ructor in Pathology in the . . . v York. Edited, with Addi- . . . of Pathology in the Cornell . . . Illustrated with 351 En- . . . Plates. Cloth. Pp. 602. . . . gravings, Inc . . . Price, \$4.00. Philadelphia and New York: Lea Brothers & Co. 1902.

This book contains a condensed statement of the principal facts of pathology, more particularly general pathological histology and pathological anatomy. That its scope and the character of its subject-matter merit the extravagant praise of the editor, we are much inclined to question. In spite of the fact that it has passed through several editions in Germany within a few years, we doubt the desirability, from a pedagogic point of view, of putting into the hands of American medical students so dogmatic and "condensed" a statement of the present knowledge as to create the impression that pathology is a dead and not a living and daily growing science. Unless supplemented by stimulating explanations and references to other works and articles by an enthusiastic teacher and by a first-rate course in laboratory work, we are inclined to fear that the ordinary student after having committed the principal parts of this book so well to memory that he could answer readily the questions of the recitation room, would think that he "knew it all." At the most this book can serve only as an introduction to the study of pathology. It is well gotten up and the illustrations are good; many of the colored ones, however, lack necessary explanation as to the staining methods used. We have not been able to find in this book a satisfactory statement of the theory of cytotoxin formation and action presented by Ehrlich, and so fruitful of valuable investigation in hemolysis, bacteriolysis and allied fields of the greatest importance to pathology.

A SYSTEM OF PHYSIOLOGICAL THERAPEUTICS. A Practical Exposition of the Methods, Other Than Drug-Giving, Useful in the Prevention of Disease and in the Treatment of the Sick. Edited by Solomon Solis Cohen, A.M. M.D., Professor of . . . peutics in the Philadelphia Polyclinic. Volume . . . Thermotherapy, Heliotherapy, and Phototherapy. Winternitz, Professor of Clinical Medicine in the University of . . . : Strasser and Dr. B. Buxbaum; and by Dr. E. Heinrich Kisch. Eighty- . . . Philadelphia: P. Blakiston's Son & Co. 1902.

This volume is devoted to hydrotherapy, thermotherapy, heliotherapy and phototherapy. It also contains notes on American springs by Guy Hinsdale and chapters on the classi-

fication of mineral waters and their distribution in the United States by A. C. Peale. The chapter on the "Practice of Phototherapy and Thermotherapy" is written by J. H. Kellogg. This volume also contains a very interesting article by Harvey Cushing on "Saline Irrigation and Infusions." A chapter on "The Methods for Therapeutic Use of Water, Heat, Cold, Light and Mineral Baths" is appended by the editor. This volume is the most useful to the general practitioner of any of the series with the possible exception of Volume VI. Part one treats of the physiologic basis of hydrotherapy, its mechanical and chemical effects on the different organs. Part two considers the technic and methods of application, describing, with splendid illustrations, the method of giving a general bath, partial baths, wet packs, the application of coils, bags, etc. Part three treats of the hydrotherapeutic measures to be applied in disease of the different organs and in the infectious diseases. The supplemental chapters take up heliotherapy, electrotherapy and the application of dry and moist heat. One chapter is devoted to the use of saline irrigations and infusions and their methods of administration. This chapter is of special practical importance to the general practitioner. While the volume contains, in order to be thorough, chapters on unimportant subjects, such as gas baths, peat baths, medicated baths, etc., it contains a sufficient amount of practical matter to render it a book of great value.

GENERAL PARESIS: Practical and Clinical. By Robert Howland Chase, A.M., M.D., Physician-in-Chief, Friends Asylum for the Insane. Illustrated. Cloth. Pp. 291. Price, \$1.75. Philadelphia: P. Blakiston's Son & Co. 1902.

Chase has taken the most modern name for the subject which he here treats and for a convenient little monograph which covers quite completely, though in rather a general way, the whole range of symptoms, pathology, treatment, etc. He has gone over the authorities and literature of the subject very thoroughly and has given in a condensed form the general facts. The book is full of illustrative cases taken from all sources. As regards the question of etiology, the author does not follow those who consider it exclusively of syphilitic antecedents, but recognizes a syphilitic insanity as closely resembling this condition. The illustrations are excellent and give one a very fair idea of the general appearance of paresis in its different stages. We notice an omission as regards the differential diagnosis. There is nothing specially said in regard to one of the most important points, namely, distinguishing the early symptoms of this disease from neurasthenia. There have been so many that have tried to point out the differences in recent literature that it would have been well had the author given some general remarks at least on this point. The fact is that it is impossible to distinguish the early stages of paresis from many cases of neurasthenia, the distinction made as regards the loss of memory, etc., is not reliable. Another criticism which we might make is that some of the abstracts or illustrations from the literature are rather too brief to be of special value or particularly to the point. This, however, is a minor matter, and as a whole the book is one that will be of service and a convenient one for consultation by those who have to do with this, unfortunately, too prevalent disease.

Marriages.

EDGAR S. HOOPER, M.D., to Miss Emma Vickers, both of Darlington, Wis., November 12.

JOHN THOMAS MOORE, M.D., to Miss Dorcas Pennock, both of Algood, Tenn., November 12.

JOHN J. HORTON, M.D., New Market, Ala., to Miss Broughton of Elora, Tenn., November 11.

HIRAM A. FULTON, M.D., to Miss Jeanette Putnam, both of Eau Claire, Wis., November 5.

ALBERT E. SELLENINGS, M.D., New York, to Miss Florence Corner of Columbus, Ohio, November 25.

JUNIUS H. WATTLES, JR., M.D., Kenosha, Wis., to Miss Amy A. Bamber of Kansas City, Mo., November 14.

SAMUEL M. D. CLARK, M.D., New Orleans, to Miss Elise Cockerham of Natchitoches, La., November 15.

CLARENCE S. MAXWELL, M.D., Mount Olive, N. C., to Miss Addie Thomas of Beaufort, N. C., November 12.

EDWARD AUGUSTUS CORCORAN, M.D., and Katherine Winifred McCarthy, M.D., both of Chicago, August 28.

GEORGE W. BREWSTER, M.D., Boston, Mass., to Miss Ellen Mackenzie Hodge of Washington, D. C., November 11.

SAMUEL K. FROST, M.D., New York City, to Mrs. Josephine Mayo Stillman of Pittsfield, Mass, in Brooklyn, November 15.

JACOB HINDEN, M.D., Strong City, Kan., to Miss Myra E. Lomas of Topeka, Kan., at Williamsburg, Kan., November 12.

ROWELL C. FAUNTLEROY, captain and assistant surgeon, U. S. Army, Madison Barracks, New York, to Miss Blanche McGonigle, at Leavenworth, Kan., November 19.

Deaths.

Walter Reed, M.D.—In the death of Dr. Walter Reed of the Army, which occurred November 23, scientific medicine has suffered a severe loss, and the profession has been bereft of a constant and enthusiastic student. Walter Reed was born in Virginia in 1857, was graduated from the Medical Department of the University of Virginia, Charlottesville, and from Bellevue Hospital Medical College, New York. He was appointed from Virginia to the Medical Department of the Army and was commissioned first-lieutenant and assistant surgeon, June 26, 1875; five years later he was made captain and assistant surgeon, and on Dec. 4, 1893, was promoted to the position of major and surgeon. At the time of his death he was at the head of the list of majors of the Medical Department of the Army. He made special studies in bacteriology at the Johns Hopkins Hospital, Baltimore, then was assigned to duty as attending surgeon at St. Paul, and from there was selected by the Surgeon General as bacteriologist in his office, and was on duty there from 1893 until the outbreak of the Spanish-American War. During that time he was a member of the board of medical officers to investigate and report on the prevalence of typhoid fever in home camps and the commission recommended the plan of collecting excreta in galvanized iron tanks, which was afterwards successfully carried out at the U. S. General Hospital, Presidio, Cal., and was followed by cessation of the disease. His especial work was in the line of preventive medicine and military hygiene. His most notable services to the science of medicine were those connected with yellow fever. He was appointed president of the board of the other members of which were Drs. Carroll and Agramonte of the Army, which met in Cuba for the study of yellow fever, and their discoveries in connection with the cause and prevention of this disease mark an epoch in medicine. Their reports have already been published in *THE JOURNAL* and show the highest degree of scientific accuracy combined with excellent discrimination. Dr. Reed was operated on for appendicitis on November 17, but did not rally from the operation, and died November 23.

Harrison Steele, M.D. Rush Medical College, Chicago, 1868, chief surgeon of the Toledo, Peoria and Western Railroad, a member of the Illinois State Medical Society, and once president of the Peoria City Medical Society, died at his home in Peoria, November 14, after a lingering illness, aged 66. The Peoria City Medical Society, at a special meeting held November 15, passed resolutions of eulogy and sorrow.

William Henry Haynes, M.D. New York University, 1878, a specialist in nervous and mental diseases and president of the Brooklyn Society for Neurology, died at his home in Brooklyn, November 15, from Bright's disease, after an illness of one year, aged 46.

William H. Crim, M.D. University of Maryland, 1870, died suddenly at his home in Baltimore, from heart disease, November 15, aged 57. He was assistant surgeon of the Fifth Regiment, Maryland National Guard, in 1872, and surgeon in 1881.

John H. Currey, M.D. Shelby Medical College, Nashville, Tenn., a surgeon in the Confederate service, in the Civil War, and postmaster of Nashville, Tenn., for several years, died at his home near Nashville, November 11, from apoplexy, aged 71.

Roger Trowbridge Atkinson, M.D. *cum laude*, Harvard University Medical School, 1898, assistant surgeon, U. S. Navy, attached to the U. S. S. *Prairie*, died at the Naval Hospital, Norfolk, Va., November 10, from malarial fever, aged 30.

Thomas E. Powell, M.D. University of Louisville, Ky., 1874, some-time president of the Vanderburg Medical Society, died at his home in Evansville, Ind., November 17, from rheumatism of the heart, aged 55.

Frederick W. Vandersloot, M.D. University of Maryland, Baltimore, 1855, for many years a practitioner of Lock Haven, Pa., died at his home in Wilmington, Del., from heart disease, November 14, aged 72.

Leroy J. Wisman, M.D. University of Michigan, Ann Arbor, 1898, a member of the Livingston County (Ill.) Medical Society, died at his home in Huntington, Ind., November 9, after a short illness.

Charles Brewster Spratt, M.D. Jefferson Medical College, Philadelphia, 1897, of Jacksonville, Fla., died, November 13, from typhoid fever, aged 32. At a special meeting of the Duval County Medical Society, November 13, resolutions were adopted.

Lundern M. Phillips, M.D. University of Vermont, 1882, a member of the Yates County (N. Y.) Medical Society, died at his home in Penn Yan, from stomach trouble, November 10, aged 44.

Ira B. Geer, M.D. formerly of Evanston, Ill., but for several years a resident of Florida, died at his home in Winter Park, November 8, from debility, following a fracture of the hip, aged 84.

James William McQuitty, M.D. Missouri Medical College, St. Louis, 1894, died at his home in Midway, Mo., from an overdose of opium accidentally administered, November 5, aged 30.

George F. Melifant, M.D. Dartmouth Medical College, Hanover, N. H., 1888, died at his home in Millville, Mass., November 4, from biliary colic, after a short illness, aged 38.

Durham M. Creel, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1878, died at his home in Industry, November 12, from exhaustion following a carbuncle on the neck, aged 83.

Gregory J. Phelan, M.D. New York University, 1847, a member of the American Medical Association, died at his home in San Francisco, November 5, from paralysis, aged 80.

A. DeV. Boggs, M.D. Texas Medical College and Hospital, Galveston, 1868, died at his residence in Marquez, Texas, November 7, from pneumonia, after a short illness, aged 58.

James Allen Meek, M.D. Jefferson Medical College, Philadelphia, 1881, died from pneumonia at his home in Bunker Hill, Ind., October 30, after an illness of two weeks, aged 74.

Charles M. Hollingsworth, M.D. University of Maryland, Baltimore, 1882, died suddenly at his home in Harrisonburg, Va., from heart disease, November 9, aged 45.

Duncan McLarty, M.D. Toronto (Ont.) University, 1867, twice mayor of St. Thomas, Ont., died at Buffalo General Hospital, a week after an operation, aged 63.

Francis T. R. Wagner, M.D. University of Gottingen, Germany, 1857, died suddenly from apoplexy, at his home in Wilkesbarre, Pa., November 1, aged 68.

Alex. H. Davidson, M.D. Tulane University, New Orleans, 1895, of Boerne, Texas, died at San Antonio, November 2, from peritonitis, after a long illness, aged 39.

William H. Kimberlin, M.D. Hospital Medical College, Kansas City, 1884, an eye specialist of Kansas City, was shot and killed by a patient, November 11.

James B. Clifton, M.D. New York University, 1857, died at his home in Lonsburg, N. C., November 2, from paralysis, after an illness of one week, aged 67.

Charles B. Riebsam, M.D. University of Pennsylvania, Philadelphia, died at his home in Madison, Wis., November 12, after an illness of one day, aged 76.

Willis Sperry, M.D. Western Reserve University, Cleveland, Ohio, 1851, died at his home in Tallmadge, Ohio, November 7, from heart disease, aged 79.

Alfred Booth, M.D. Harvard University Medical School, Boston, died at his home in Springfield, Mass., November 16, from senile debility, aged 78.

Newell G. Tullis, M.D. Medical College of Georgia, Augusta, 1872, died at his home in Thomasville, Ga., November 11, after a long illness, aged 50.

David Lyle, M.D. Medical College of the State of South Carolina, Charleston, 1868, died at his home in the Edgemoor Section, S. C., November 10.

J. Moore Hart, M.D. Trinity Medical College, Toronto, 1871, of Toronto, while hunting in Muskoka, died suddenly, November 10, from apoplexy, aged 52.

J. S. Spangler, M.D. College of Physicians and Surgeons, Keokuk, Iowa, died at his home in Ute, Iowa, November 5, from pneumonia, aged 43.

H. M. Craton, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1867, of Jesup, Iowa, died at Downing, Wis., November 18, aged 76.

William Henry Hosmer, M.D. Dartmouth Medical College, Hanover, N. H., 1838, died at his home in Penacook, N. H., November 15, aged 88.

George S. Dodge, M.D. Harvard University Medical School, Boston, 1881, died at his home in West Acton, Mass., November 2, after a long illness.

Ransom R. Crothers, M.D. University of Maryland, 1873, at Colora, Md., November 8, from heart disease, after an illness of two weeks, aged 57.

John C. Hardy, M.D. Columbus (Ohio) Medical College, 1881, died at his home in Marietta, Ohio, from hemorrhage of the stomach, aged 47.

Adelbert E. Burdick, M.D. New York University, 1873, died at his home in Manistique, Mich., November 12, from tuberculosis, aged 56.

Junius H. Wattles, M.D. University Medical College, Kansas City, Mo., 1897, died at his home in that city, November 9, aged about 50.

Arthur Britnall, M.D. Western Reserve University, Cleveland, Ohio, 1881, of Liverpool, Ohio, died recently at Lakeside Hospital, Cleveland.

Samuel C. Fechtig, M.D. University of Pennsylvania, Philadelphia, 1846, died at his home in Wellersburg, Pa., November 2, aged 80.

George W. Fringer, M.D. Missouri Medical College, St. Louis, 1869, died at his home in Pana, Ill., November 17, aged 67.

William P. Kennedy, M.D. University of Maryland, Baltimore, 1885, died at his home, in Warsaw, N. C., November 9.

Miscellany.

Clippings from Lay Exchanges.

HOW IS THE PATIENT?

"Last Saturday, Dr. — performed an operation . . . which, from a scientific standpoint, places former recorded operations in the dark. — has been afflicted with plural effusion of the right lung. Dr. — inserted the pump, and after extracting about a pint was inclined to let it rest at that, but the patient was not in the least fatigued so he continued and removed the entire accumulation, 68 ounces or more than half a gallon.

"Dr. — has the bottle and its contents on exhibition. The quantity removed is double what the authorities claimed to be a safe operation."—*Iron (Cal.) Echo*, May 10, 1902.

SEVERAL SPINAL JOINTS REMOVED.

"The physicians at the City Hospital yesterday performed the operation of laminectomy upon —, an Italian, in hopes of relieving him of paralysis caused by a broken back. . . . The physicians removed several joints from the backbone to relieve the pressure against the spinal cord which caused the paralysis."—*Cincinnati (Ohio) Commercial Tribune*, April 25, 1902.

SLIPPED INNOMINATE.

"Mr. B— had been examined and treated by a number of prominent physicians but the cause of his trouble which was usually diagnosed as sciatica had been overlooked. His condition was one that osteopaths term 'slipped innominate,' the ilium on the affected side being slightly dislocated upward and backward."—*Ludington (Mich.) Record-Appeal*, May 16, 1902.

A DARNED RUPTURE.

"Dr. — and his assistants placed about twenty-five feet of silver wire in —'s abdomen in darning a rupture of the anterior abdominal wall."—*Chicago Chronicle*, April 25, 1902.

THE WISCONSIN FOR HAHNEMANN.

"Dr. —, Dean of Hawverawnn Medical college was in town on Thursday. . . ."—*Janesville (Wis.) Gazette*, June 1, 1901.

ERAMIC COMA.

"Dr. J. E. McD— died at the family residence. . . . The immediate cause of death was eramic coma the same being brought on by catarrhal jaundice and kidney and bladder trouble."—*Quincy (Ill.) Journal*, April 22, 1902.

State Boards of Registration.

Prosecution in Kansas.—Dr. H. W. Roby, Topeka, secretary of the Kansas board, is to be congratulated on his campaign against unlicensed practitioners in that state. Information against seventeen of these in Kansas City, Kan., has been filed, and thirty more are to be proceeded against in that city.

Osteopathic School Not Reputable.—Some time ago, one M. V. Aldrich was refused license in Goshen, Ind., because he did not have a diploma from a college of the required standing. He sued the Indiana board and was defeated. On appeal the decision against him has just been reaffirmed. The evidence in the case showed that the college which Mr. Aldrich attended, the National School of Osteopathy, Chicago, is not what the board considers "reputable."

Illinois April Examination.—The following is a report of the examination held by the Illinois State Board of Health, at Chicago, April 9-11, 1902, as supplied by Dr. J. A. Egan, secretary, Springfield: Written examination; subjects, 11; questions, 110; percentage required to pass, 75; total number examined, 98; passed 93; failed, 5.

Association News.

Report on the Pathologic Exhibit.

Dr. F. M. Jeffries, New York, Chairman of the Committee on Pathologic Exhibit at the Saratoga meeting of the American Medical Association, held June 10 to 13, 1902, makes the following report:

From a standpoint of attendance as well as the extent of the materials brought to Saratoga the exhibit was an undoubted success this year, even exceeding the expectations of those interested in its achievement.

The Committee wishes to express its sincerest gratitude to those by whose efforts this success was attained. Those not familiar with museum and laboratory work can form no appreciation of the amount of labor involved in the selection, preparation and shipment of an exhibit. It means labor, too, for which not even an indirect monetary remuneration can be expected and accordingly are the thanks of the American Medical Association as a whole all the more necessary.

Those who have felt that such an exhibit was not only impractical but unnecessary have now had three successful exhibits to point out their errors. The Scientific Exhibit is not intended to be of interest alone to laboratory men—this is indeed a small part of its scope. It is true the laboratory man finds here a mint of information in his line, especially in the art of mounting and preserving museum specimens. He comes in contact with workers in the same line from all parts of the continent and leaves the exhibit with a host of new ideas which he could never have attained by a perusal of all current literature.

But what of the greater number of visitors—the practitioners, be they general practitioners, surgeons or specialists? No matter what his specialty the medical man could find here unlimited material, all grist for his mill. No one museum or laboratory could afford him the practical information that awaited him here. And notwithstanding the statement made in the opening paragraph concerning the attendance, the writer feels that the members did not take advantage of the exhibit as they should. There were scores present in Saratoga who did not visit the exhibit. Many of those who called did so because friends discovered (?) the exhibit and went out and brought them in.

The location this year was ideal in every respect and should be remembered by future committees on arrangements. If the attendance is not all that could be wished in such quarters much less must be expected in rooms that are inaccessible or otherwise undesirable.

The exhibit was housed in the ball-room of Congress Hall, one flight up and fronting on the main street. We had a sign up across the sidewalk beneath which every visitor had to pass in order to get to the bureau of registration, Association post-office, etc.

The scope of the exhibit was even greater than that of 1900, though numerically it was not so great, comprising as it did 1,528 specimens as opposed to 2,130 at St. Paul. It will be observed that the number of exhibitors is surprisingly small when the number of exhibits is considered.

It was the effort of the committee this year to avoid the necessity of classification at the exhibit by having each exhibitor confine his selections as far as possible to materials illustrative of one theme, as it were. By this means each exhibit was left intact, which was not only a source of satisfaction to the exhibitors, but was a means of saving much labor when time was a consideration.

In the opinion of the committee future exhibits should not be larger than the one at present under consideration. In the first place a larger exhibit might be uninviting to the visitor because of its extensiveness and the labor involved in its inspection. Secondly, a larger exhibit could hardly be accommodated with satisfactory housing and thus cause the exhibits to be cramped and crowded. And finally, future exhibits must be considered and we must not put all our eggs in one basket, as it were.

Though the exhibit is under the auspices of the Section on Pathology and Physiology, the physiologic exhibit was woefully meager and yet the physiologic laboratories and classrooms could furnish valuable materials in almost unlimited quantities. The attention of future committees is called to this feature that they may put forth extra efforts to secure such exhibits and thus greatly enhance the usefulness of the department.

The attention of future committees is finally called to the necessity of having an attendant at the door of the hall to keep out those having nothing but morbid curiosity to satisfy. At Saratoga it was found that the local population became greatly interested, and boys, girls, men and women began to fill the hall until it became necessary to station a man at the door, and if this man's experience counts for anything, future attendants should be of the strenuous sort.

Our thanks are due to the Albany Medical College and Ernst Leitz for the loan of fifty microscopes during the session.

LIST OF EXHIBITS.

COLLEGE OF PHYSICIANS, MILWAUKEE: THOMAS FITZGIBBONS.
Photographic illustrations of tumors removed..... 35

Such a collection taken in conjunction with the microscopic sections and histories would comprise a most valuable source of information.

DR. BYRON ROBINSON, CHICAGO.
Skiagraphs of injected subjects demonstrating vascular systems 15

CORNELL MEDICAL COLLEGE, DR. B. H. BUXTON.
Microphotographs and enlargements, tissues and bacteria..... 50

This collection was admirable in every respect and represents the highest type of skill and perfection in laboratory photography.

CORNELL MEDICAL COLLEGE, DR. J. EWING.
Confluent hemorrhagic variola, diphtheritic bronchitis and lobular pneumonia: 1
Conglomerate eruption (full pustular stage)..... 1
Confluent variola, diffuse and hemorrhagic..... 1
Confluent scabbing (forearm)..... 1
Bullous: 1
Secondary hemorrhagic variola, diphtheritic tracheitis..... 1
Acute ulcerative endocarditis (variola)..... 1
Late discrete variola (trachea)..... 1
Conglomerate hemorrhagic 1
Punctate hemorrhagic in a bleeder..... 1
Various hemorrhagic in a bleeder..... 1
Conglomerate eruption—diffuse, hemorrhagic..... 1
Scanty discrete variola—late scarlatina—form eruption..... 1
Various stages of eruption—hemorrhagic, petechiae..... 1
Early confluent (trachea)..... 1
Primary hemorrhagic (kidney, 2 cases)..... 2
Primary hemorrhagic (trachea, 2 cases)..... 2
Early secondary hemorrhagic (trachea)..... 1
Full pustular eruption (infant)..... 1
Confluent secondary hemorrhagic..... 1
Confluent secondary hemorrhagic (black smallpox)..... 1
Primary hemorrhagic (negro)..... 1
Human glands (pustular lesions of the skin)..... 1
Variola (rib)..... 1
Primary hemorrhagic (death on third day of disease)..... 1
Confluent secondary hemorrhagic (trachea)..... 1
Diphtheritic lesions of the trachea. Peritracheal edema and death after tracheotomy: 1
Primary hemorrhagic (trachea)..... 1
Primary hemorrhagic (colon)..... 1
Discrete lesion of trachea..... 1
Acute ulcerative endocarditis (variola)..... 1

Confluent pustular..... 1
Flat bullous and sero-pustular eruption (child)..... 1
Hemorrhagic and necrotic orchitis (variola)..... 1
Mesenteric lymph nodes (child) (variola)..... 1
Total 34

CORNELL MEDICAL COLLEGE, DR. JOHNSTON.
Melanoma: Tumor and metastases in skin, liver, lungs and heart..... 6
Spindle-celled Sarcoma: Pedunculated growth from skin of thigh, 20 years' standing..... 1
Endothelioma from below inferior maxilla..... 1
Total 8

BOSTON UNIVERSITY SCHOOL OF MEDICINE, O. R. CHADWELL AND W. H. WATERS.
Gross pathologic specimens preserved in Kaiserling's fluid and mounted in gelatin in Petri dishes..... 88
Too much can not be said in praise of this collection or of this method for mounting tissues for teaching purposes. The natural colors and markings are retained, close inspection is admitted.

DARTMOUTH MEDICAL SCHOOL.
Fibroma of uterus, weight 42 pounds..... 1
Malignant adenoma of fundus uteri..... 1
Congenital cystic kidney..... 1
Spindle-celled sarcoma, lower jaw..... 2
Carcinoma of omentum..... 1
Epithelioma of cervix uteri..... 3
Carcinoma of colon..... 1
Total 10

DR. D. A. KUYE, RICHMOND, VA.
Gross and microscopic specimens of tubercular iritis in girl 11 years of age..... 6
EDWARD GIBBS, X-RAY LABORATORY, N. Y. UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE.
X-ray illustrations of bronchial tree in situ injected with fine bird shot 7

DR. H. G. GRAHAM, CHICAGO.
Microscopic demonstrations of diatomace and bacteria..... 14
DR. WINFIELD S. HALL, CHICAGO.
Chest pantograph for measuring contours of chests..... 1

DR. LEO LOER.
Sarcoma of rat with drawings from microscopic specimens... 3

N. Y. HOSPITAL FOR RUPTURED AND CRIPPLED—F. M. JEFFRIES.
Ostitis of vertebrae..... 5
Multiple ostitis 1
Muscular cavanoma 1
Hip-joint disease 2
Osteo-myelitis, femur and tibia..... 1
Ankylosis of knee-joint..... 1
Tubercular ostitis, lower end of femur..... 2
Tubercular ostitis os calcis..... 1
Double hip-joint disease, bony ankylosis..... 1
Total..... 15

DR. A. D. MEWBORN, NEW YORK CITY.
Cultures of fungi of skin diseases grown on media in Erlenmeyer flasks 77
Photographs of same..... 16
Lantern slides of same..... 13
Colored charts illustrating skin lesions..... 9
Slides of drop cultures of trichophytos, microsporium, achorion oospora, etc. 25
Bodin's method of making drop cultures of trichophytos..... 1
New method of making drop cultures of the hyphomycetæ..... 1
Total..... 142

This collection gave evidence of a great amount of labor requiring skill and patience and embracing a department of biology greatly neglected in this country. Dr. Mewborn is to be congratulated on the results he has attained.

MUSEUM MOSES TAYLOR HOSPITAL, DR. J. M. WAINWRIGHT, SCRANTON, PA.
Joint-mice 2

HARVARD MEDICAL SCHOOL, DR. W. T. PORTER.
Exhibit of some new physiologic apparatus..... 12

HYGIENIC LABORATORY, U. S. MARINE-HOSPITAL SERVICE.
Cultures of tubercle bacilli on various fruits and vegetables as nutrient media 72
Cultures of acid-proof bacilli resembling tubercle bacilli grown on various fruits and vegetables as nutrient media..... 72
Total..... 144

MEDICAL CLINIC OF RUSH MEDICAL COLLEGE, DR. FRANK BILLINGS.
Series of microphotographs of spinal cord lesions..... 20
THE UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE, LEON T. LE WARD.

Larynx, edema of..... 2
Larynx, syphilitic ulceration of..... 1
Larynx, asphyxia due to lodgment of collar button..... 1
Lung, from 2-year-old child, showing acute lobar pneumonia and fibro-purulent pleurisy..... 1
Lung, tuberculosis, acute or chronic..... 1

Lung, acute phthisis	1
Lung, chronic tuberculosis, showing large hemorrhage.....	1
Liver, echinococcus multilocularis, fourth in the U. S.....	1
Liver, solitary abscess (amebic colitis).....	1
Kidney, hypernephroma.....	1
Kidney, chronic tuberculosis	1
Kidney, embolic abscesses	1
Kidney, renal calculi	1
Kidney, cystic (congenital)	1
Kidney (pair), post-scarlatinal nephritis.....	1
Kidney (pair), fatty and parenchymatous degeneration.....	1
Bladder, papilloma	1
Brain, sarcoma of right optic thalamus.....	1
Brain, endothelioma of dura indenting brain.....	1
Brain, atheroma of cerebral vessels.....	1
Brain, hemorrhage into cerebellum.....	1
Brain, glioma of frontal lobe.....	1
Spleen, marked millary tuberculosis.....	1
Fibroid uterus complicating pregnancy.....	2
Carcinoma of cervix uteri complicating pregnancy.....	1
Fetus in utero—seven weeks' gestation.....	1
Fetus with membranes, about five weeks' gestation.....	1
Placenta from case of triplets.....	1
Encephalic monster, two-faced.....	1
Cephalothoracopagus	1
Heart, chronic interstitial myocarditis.....	1
Heart, fatty degeneration.....	1
Melano-sarcoma of humerus.....	1
Sarcoma of small intestine.....	1
Carcinoma of stomach.....	1

H. J. PRENTICE.

Radiographs, showing bronchial tree <i>in situ</i> , injected with fine bird shot	7
---	---

L. B. GOLDHORN.

Photomicrographs and drawings of blood parasites stained by the Goldhorn method.....	23
Total.....	67

This collection from the University and Bellevue Hospital Medical College, comprising as it did such a diversity of material, rich in rare specimens, was worth all the trouble encountered in getting up the exhibit. The laboratory work in its preparation represented the highest type.

COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO, ILL.

Gangrene specimens	7
Liver specimens	6
Heart specimens	10
Pelvic specimens	24
Brain specimens	16
Symphys apus	1
Hare lip and cast.....	1
Double aorta.....	1
Head sections.....	42
Comparative anatomy: ostrich, bear, turtle, opossum, snake, pig, ox, horse, deer, sheep.....	20
Pelvic skiagraphs (Robinson).....	11
Students' theses.....	36
Total	175

This was one of the most extensive exhibits presented. Particularly valuable were the dissections and head sections. These were of a nature and accuracy rarely encountered, and in justice to all concerned it should be stated that they were prepared by the students of the college.

The 36 cases of theses represent the regular work of the students.

DR. ROBERT ABBE, NEW YORK.

Chronic latent appendicitis.....	10
Obliterating appendicitis.....	10
Single tight strictures, appendix.....	10
Concretions beyond strictures, appendix.....	5
Gangrene beyond strictures.....	5
Acute septic follicular ulcer of appendix.....	14
Graphic and easy method of illustrating and demonstrating retrograde changes in inoperable cancer of breast during treatment with x-ray, by means of plaster casts.....	3
Total	57

This collection is not only remarkable for its elaborateness, but for the excellency of their mountings, affording as they do perfect demonstrations of the various lesions of the appendix.

MILWAUKEE MEDICAL COLLEGE, DRS. WUERDEMANN AND BLACK.

Sections of eye in glycerin.....	80
Collection of photographs illustrating a study of multiple angio-sarcoma	1
Pathological specimens.....	7
Drawings	7
Microscopical mounts.....	7
Photographs illustrating eye lesions.....	36
Total	138

Particularly worthy of mention in this collection was the series of mounts of the eye.

DR. EVANS, LA CROSSE, WIS.

Illustrative cases of cholelithiasis.....	12
These sets of stones were neatly displayed in a case specially prepared and afforded an excellent demonstration of this lesion.	

BROOKLYN HOSPITAL, N. Y., DR. SHERWOOD.

Photographs of patient with pellagra or Italian leprosy.....

DR. T. C. MARTIN, CLEVELAND, OHIO.

Pathologic specimen, congenital valvular obstipation.....
Drawings, lesions rectal mucosa.....

ALBANY MEDICAL COLLEGE.

Skull: Cranial syphills.....	1
Inferior maxilla: Necrosis from absorption of phosphorus through cavity of decayed tooth.....	1
Spinal column: Caries of vertebrae.....	1
Ankylosis of vertebrae.....	1
Fracture and distortion of vertebrae.....	1
Tuberculosis of vertebrae.....	1
Fracture of vertebrae.....	1
Humerus: Ankylosis with scapula.....	1
Humerus: Fractures	1
Elbow-joint ankylosis	1
Radius and ulna: Syphilitic hypertrophy.....	1
Radius and ulna: Syphilitic periostitis.....	1
Radius and ulna: Exostosis with ankylosis.....	1
Radius and ulna: Fracture	1
Femur: Simple fracture	1
Femur: Fracture and distortion.....	1
Femur: Impacted fracture of head.....	1
Femur: Oblique fracture	1
Femur: Fracture and necrosis.....	1
Femur: Fracture and absorption.....	1
Femur: Necrosis	1
Femur: Caries and necrosis.....	1
Femur: Abscess and caries.....	1
Femur: Distortion and softening.....	1
Femur: Syphilitic hypertrophy	1
Morbus coxae	1
Femur and tibia: Arthritis deformans.....	1
Knee-joint caries	1
Knee-joint ankylosis	1
Tibia: Fracture	1
Tibia: Distortion and softening.....	1
Tibia: Necrosis	1
Tibia: Caries and atrophy.....	1
Tibia: Syphilitic hypertrophy	1
Tibia and Fibula: Distortion and softening.....	1
Tibia and Fibula: Fracture	1
Tibia and Fibula: Fracture without treatment.....	1
Tibia and Fibula: Periostitis from chronic ulcer of leg.....	1
Tibia and Fibula: Caries	1
Foot: Caries of tarsus, metatarsus and phalanges.....	1
Total.....	

This extensive collection consisted of the dried specimen neatly mounted on wooden bases on each of which the diagnosis was plainly printed. In the writer's experience, there are no medical colleges which possess so extensive and comprehensive a collection of specimens illustrative of bone lesions.

CINCINNATI HOSPITAL MUSEUM.

Lungs: Normal.....	1
Lungs: Sarcoma	1
Lobar pneumonia, red hepatization.....	1
Lobar pneumonia, gray hepatization.....	1
Simple pleurisy	1
Tuberculosis	1
Heart lesions	1
Total.....	

NEW YORK POLYCLINIC LABORATORY, F. M. JEFFRIES.

A collection of interesting microscopic mounts:	
Lymph-gland infiltrated with thyroid tissue.....	1
Endothelioma of breast.....	1
Sclerosis of penis with ossification.....	1
Adeno-chondroma of parotid.....	1
Large round celled sarcoma of leg.....	1
Dermatitis papillaris capillitii.....	1
Struma supracrenalis of kidney.....	1
Syphilis of tongue	1
Epithelioma from a horse.....	1
Mixed celled sarcoma from a canary bird.....	1
Fatty embolus in lung following fracture of rib.....	1
Granular epidymitis	1
Deciduoma malignum	1
A rare form of hemorrhagic sarcoma from a boy with multiple tumors	1
Colloid carcinoma primary in breast.....	1
Struma hyperplastica, thyroid	1
Intramural fibroma, intermural myoma and epithelioma, all from one uterus.....	1
Gumma of intestine.....	1
Tubercular uterus from child.....	1
Muscular cavernoma	1
Carcinoma of appendix, primary.....	1
Petechial hemorrhage cerebellum, malaria.....	1
Endothelioma of lung.....	1
Total.....	

INDIANA STATE MEDICAL SOCIETY, FRANK B. WYNN, INDIANAPOLIS.

Aneurisms.....

These represented the extremes in size and the various types. One very large one showed lamination most beautifully.

Vesical calculi

One of these was formed about chewing gum; another about a pipe-stem; one weighing 4¾ ounces was removed from a patient of ten years; and 35 of them were obtained by operation in a missionary hospital in Persia.

Enteroliths..... 4
These were as large as small hen's eggs; one was sloughed through the abdominal wall, two passed by the rectum, and one obtained postmortem.

Hair balls, renal calculi, etc., from lower animals..... 10
Very remarkable in this group was an immense hair-ball ten inches in diameter, composed of hog-hair and obtained from an ox which had grazed upon a pasture field where hog-hair had been strewn.

Miscellaneous specimens 8
Total..... 72

Among other interesting things, this contained a mortar which belonged to the surgeon of Lafayette; also a skull trephined by Baron Larrey, chief surgeon of Napoleon I, in his campaign against Moscow.

The Indiana State Medical Society is entitled to the distinction of being the pioneer in the pathologic exhibit idea, having had such an exhibit at its annual meetings for five years past, and being the first to make an exhibit at the meeting of the American Medical Association. This was at the Columbus meeting in 1899, when some 300 specimens were shown. The good example set was followed by the inauguration of a Pathologic Exhibit at the Atlantic City meeting, and the adoption of the idea by other state societies.

DR. J. F. SCHAMBERG AND DR. J. F. WALLIS, PHILADELPHIA.
Wax models of cutaneous diseases..... 21

DR. B. M. RANDOLPH, PHILADELPHIA.
New cabinet for microscopic slides, designed by the late Thos. S. Kirkbride 1

DR. GAYLORD T. CLARK, MEDICAL DEPARTMENT, SYRACUSE UNIVERSITY.
Apparatus demonstrating the action of the aortic and mitral valves..... 1

This apparatus, designed and made in the college, most effectually attained the ends desired and allowed the complete observation of the valves in action. A bullock's heart was mounted and with cleverly devised water tubes systolic and diastolic rhythm was obtained. This exhibit proved to be one of the most attractive exhibits.

PATHOLOGIC LABORATORY, RUSH MEDICAL COLLEGE, CHICAGO.
Cystic sarcoma of bone..... 1
Cardiac cirrhosis..... 1
Chronic hyperplastic splenitis..... 2
Hyperplastic tuberculosis of great omentum..... 1
Unilateral arteriosclerotic atrophy of kidney..... 1
Papillary tumor of the gall bladder, accompanying calculi..... 1
Chronic caseous nodular tuberculosis of the liver..... 1
Secondary carcinoma in the subpleural lymph..... 1
Chronic hyperplastic pleuritis..... 1
Polypus of the pharynx..... 1
Septic thrombo phlebitis of the ovarian vein..... 1
Diffuse infiltrating and nodular secondary melano-sarcoma of the liver..... 1
Primary diffuse round-celled sarcoma of the pericardium..... 1
Chronic hyperplastic tuberculosis of the cecum..... 1
Metastatic melano-sarcoma of the lymph nodes in the ileum..... 1
 poisoning..... 1
 stomach..... 1
 in lung of dog..... 1
Cast of trachea and bronchi..... 1
Primary carcinoma of the lung..... 1
Primary carcinoma of the esophagus..... 1
Cysticercus cellulosus from brain and spinal cord..... 1
Metastatic carcinoma nodules of the diaphragmatic surface of the left lung..... 1
Multiple fibromas of the left sciatic nerve..... 1
Multiple fibromas of the right sciatic nerve..... 1
Ascending pyelonephritis with carcinoma of bladder..... 1
Tuberculous cysto-utero-pyelitis..... 1
Chronic hyperplastic splenitis with large areas of caseous tuberculosis..... 1
Primary sarcoma of the spleen..... 1
Chronic tuberculosis of the skin..... 1
Chronic gastritis with production of the "état mamelonné"..... 1
Skeleton of a Madura foot..... 1
Bovine actinomycosis, inferior maxilla..... 1
Specimen illustrating adaptation of the tail for support following traumatic removal of right hind extremity in a rat..... 1
Sarcoma of the spinal meninges..... 1
Fat necrosis from a case of gangrenous pancreatitis..... 1
Cyst of the urachus..... 1
Hemorrhagic pancreatitis..... 1
Sarcoma of the bladder with calculus..... 1
Esophageal diverticulum formed by extension of an abscess of a peribronchial lymph gland..... 1
Slices of tumor-like growth occurring in bovine actinomycosis..... 1
Hypernephroma..... 8
Hypertrophy of the prostate, diverticula of the bladder, vesical calculi..... 1
Malignant hypernephroma..... 1
Metastatic growth with myocardium..... 1
Perforation of the bronchus from suppuration in a peribronchial lymph gland..... 1
 of the skin..... 1
 abortion..... 1
 dules ileum..... 1

Primary carcinoma of the Fallopian tube..... 1
Ulcerative colitis from a case of amebic dysentery..... 1
Stomach from a case of carbolic poisoning..... 1
Dentulous cystoma inferior maxilla..... 1
Multiple secondary carcinoma of the lung..... 1

Total 62

This was one of the most extensive and valuable exhibits. The collection embraced material covering a wide field of research-work and the mounts were of the highest type of perfection.

DR. J. F. SCHAMBERG, PHILADELPHIA.
Skin of hemorrhagic smallpox, preserved in Kaiserling's fluid in hermetically sealed cells..... 1
Skin of smallpox, fourth day..... 1
Skin of smallpox, seventh day..... 1
Skin of smallpox, eighth day..... 1
Skin of smallpox, hemorrhagic..... 1

Total 5

DR. M. K. KASSABIAN, IN CHARGE OF ROENTGEN-RAY LABORATORY OF THE MEDICO-CHIRURGICAL COLLEGE AND HOSPITAL OF PHILADELPHIA.

A series of skiagrams: Various stages of pulmonary tuberculosis, aneurism of aorta, displacement of heart, foreign bodies in brain and eye, renal and vesical calculi, every variety of fracture and dislocation and endeavors with injected circulatory and respiratory systems..... 100

DR. DAVID RIESMAN, PHILADELPHIA.
Mounted sections of pancreas, lung and kidney with calcareous infiltrations from a boy aged 3 years with synostosis of skull 3

DR. HERBERT C. EMERSON, SPRINGFIELD, MASS. (PRIVATE COLLECTION.)
A series of appendices mounted in Kaiserling's fluid and showing various pathologic lesions..... 30
A series of charts showing laboratory outfits (diagnostic) for pathologic, hematologic and bacteriologic specimens..... 8

Total 38

Very attractive was the collection of appendices which were mounted in a manner quite original and calculated to best show the specimens.

LABORATORY OF THE STATE LIVE-STOCK SANITARY BOARD OF PHILADELPHIA.
Spleen of calf inoculated with human tubercular sputum..... 1
Tissues of rabbit with nodules from inoculation with timothy grass bacillus..... 1
Lung of dog inoculated with culture of tuberculosis from mesenteric gland of child..... 1
Viscera of monkey fed with cultures of tubercle bacilli from mesenteric gland of child..... 1
Lung of cow showing cavity formation, infected experimentally by feeding..... 1
Tubercular larynx of cow..... 1
Lungs of pig fed with cultures of human tubercle bacilli..... 1
Various organs showing results of experimental work with cultures of human tubercle bacilli..... 10
Viscera of monkey fed with bovine tubercle bacilli from milk..... 1
Lung of goat infected with human tubercle bacilli..... 1

GRAND TOTAL..... 1528

Medical Organization.

Membership in State Societies.

One of the fundamental principles in the new plan of organization—new except in a few states—is that membership in the county society carries with it membership in the state society. A few physicians—happily only a few—object to this. Not that they object to the membership, but they are not willing to pay, directly or indirectly, their share of the expenses incurred by the state body. As this is the main objection, on the part of those who have not heretofore supported the state society, to the systematic plan now going into effect, it may be well to consider it for a moment.

In the first place we must have a clear appreciation of the duplex character of the reorganized state society. It will consist of: 1, a legislative or business body, called in most states the House of Delegates; 2, the scientific branch, which thus far has received no distinctive name, but which we may call the General Meeting.

THE HOUSE OF DELEGATES.

The House of Delegates is made up of duly elected representatives of the county societies. This body makes and amends the constitution and by-laws, transacts all the business, elects the officers, etc. It will, if it does its duty, see that laws affecting the profession are enforced, and will engage lawyers for this purpose. It will, if it thinks it ad-

visible, appoint committees to try to have the laws regulating medical practice made what they should be, to inquire into conditions affecting the profession and the public, and to aid the county societies to be of practical benefit to their members and to the profession. In a word, its function will be to represent and act for the profession of the state in every way as circumstances dictate, and as conditions require, and to spend money as may be necessary to accomplish these objects. In point of fact, and this should be clearly and distinctly understood, the House of Delegates of a state society is the state society in the eyes of the law. This being so, then it naturally follows that the members of the state society, strictly speaking, are those who are elected as such by the component societies. We realize that this is a quibbling with terms, and that few will be willing to acknowledge that the General Meeting is not the state society. We state the matter in this way, however, more to emphasize the importance of the legislative body in the eyes of the law over the General Meeting.

THE GENERAL MEETING, OR THE STATE SOCIETY.

The functions of the General Meeting are scientific, or educational and social, and are thus entirely distinct from those of the House of Delegates. The General Meeting transacts no business and spends no money, neither is there any expense connected with the meeting, except that which is incurred in getting up and circulating the program—a very small item. Usually the halls for the meetings are provided by the local profession, assisted or not by the citizens. In other words, there is so little expense connected with the General Meeting as a scientific body that practically no "state society dues" would be necessary to keep it up. (We purposely omit the consideration of the expense of publishing the papers and discussions, whether in journal or book form, leaving that for a future consideration.)

Who are members of this larger body, the state society or General Meeting, whichever title is preferred? Who has a right to attend its meetings? Under the new scheme of organization every member of every component society has a right to attend and participate in these meetings; in other words, is a member of the state society. No certificate will be required of a member of a county society when he attends the state society meeting, no formal application, only his name must be on the roster of the county society of the county in which he lives. One would think that there could be no objection to this. One of the great desires of those who have charge of scientific meetings, whether national, state or district, whether special or general in their character, is to have a large attendance. Consequently, the state societies in the past have striven in every way possible to get a large attendance, and even those who were not members were invited to attend the meetings, although they had no right to take part. Every respectable physician has been made welcome, and even a homeopath or an eclectic would not be ordered out should he happen in. No one will deny that it should be the object of the officers of a state society to get every physician in the state to attend its meetings, for the reason that it will be beneficial to all concerned. Neither the payment of dues nor going to the trouble of making formal application should be put in the way of those whose attendance is desired. The state society is not a select body, and never has been so considered. The majority of the states have always accepted, without reference to a committee or anything else, those who come delegated from a county society. The fact that they were members of such a society was satisfactory evidence that they were fit for membership. Hence, we can not understand that there can be any possible objection to allowing every physician who belongs to a county society to attend the General Meeting—the state society—without any formality.

The only objection is that referred to at the beginning of this article, namely, that certain members of county societies object to paying their share of the expenses. And yet how narrow, how selfish, and how unappreciative of his duties as a member of a great profession must be the physician who would refuse to contribute his share toward the sum required to

carry on the work hinted at above, a work that is as much for his interest as for the good of any other member, whether he attends and gets the benefit of the scientific general meetings or not.

To recapitulate:

1. The House of Delegates is made up of those selected by the county societies, every member having a voice in this selection. It thus becomes the mouthpiece of the members of the county societies to voice their sentiments and to express their desires. At the same time, it does or does not, according to the wishes of the county societies, carry out certain works which require the expenditure of money. It is only right that every physician who has a choice in electing those who constitute the House of Delegates should pay his share of the money thus appropriated.

2. The annual meeting of the state medical society—the General Meeting—is a convention of the members of the county societies for social, scientific and educational purposes. Every member in good standing of a component society is a member of this state society, and has a right to attend, and participate in its deliberations. The expense connected with the general meeting is practically nil.

3. Since there is practically no expense connected with the annual meeting of the state society—the General Meeting—practically none of the "state society dues" will be needed for the purpose of paying such expense, and the "state society dues" will be used for the benefit of the profession of the whole state. Hence, because a physician never attends the annual meeting is no reason for his not paying his proportion of the funds used for the general good of the profession, himself included.

Vermont State Medical Society.

Commenting on the recent meeting of the Vermont State Medical Society, which was the first one held since that body was reorganized, the *Vermont Medical Monthly* says, editorially: "The House of Delegates provided by the reorganization, assumed the business of the society, and much satisfaction was felt for the new régime. All business was transacted smoothly and unobtrusively, without the slightest interference with the scientific work of the society. The personnel of the House of Delegates assures the success of the plan, for it is evident that the highest interests of the society are in safe hands."

Cass County (Mo.) Medical Society.

Pursuant to a call issued by Drs. Jacob S. Triplett and M. P. Overholser, Harrisonville, the physicians of Cass County met at Harrisonville, November 6, and organized a county medical society, in accordance with the rulings of the State Judicial Council. The following officers were elected: President, Dr. Harold Jerard, Pleasant Hill; vice-presidents, Drs. Frank B. Ellis, Garden City, and George E. Elly, West Line; treasurer, Dr. Aaron R. Elder, Harrisonville, and secretary, Dr. Jacob S. Triplett, Harrisonville. Cass County formerly was in the territory of the Hodgen Medical Association, composed of the counties of Cass, Bates and Vernon.

Cass County (Ill.) Medical Society.

The physicians of Cass County met in Virginia, November 13, and formed a county medical society. Dr. Carl E. Black, Jacksonville, called the meeting to order. The constitution and by-laws suggested for county societies by the American Medical Association were approved. The following officers were elected: President, Dr. James A. Glenn, Ashland; vice-president, Dr. George Bley, Beardstown; secretary, Dr. John A. McGee, Virginia, and treasurer, Dr. John G. Franken, Chandlerville.

Allegan County (Mich.) Medical Society.

The physicians of this county met at Allegan, November 6, and organized this society. Drs. William H. Haughey, Battle Creek; George W. Lowry, Hastings, councilors, and James M. Elliott, Hickory Corners, members of the Michigan State Medical Society, were present to assist in the work. The officers elected were: President, Dr. Walter H. Bills, Allegan; vice-president, Dr. Milton Chase, Otsego, and secretary and treasurer, Dr. William S. Albright, Allegan.

Ingham County (Mich.) Medical Society.

On November 13, the Central Michigan Medical Society met at Lansing and disbanded. The members immediately organized the Ingham County Medical Society, adopted the constitution and by-laws recommended by the American Medical Association, and elected the following officers: Dr. Sidney H. Culver, Mason, president; Dr. Harry A. Haze, vice-president, and Dr. L. Anna Ballard, Lansing, secretary and treasurer.

Medical Society of Renville-Chippewa-Lac qui Parle and Yellow Medicine Counties, Minnesota.

Physicians of these counties met at Granite Falls, October 22, with Dr. William S. Fullerton, St. Paul, state organizer, and formed this society, with the following officers: President, Dr. William M. Stratton, Granite Falls; vice-president, Dr. Charles E. Rogers, Montevideo; secretary, Dr. Eric O. Gier, Madison, and treasurer, Dr. Franklin J. Cressy, Granite Falls.

Oconto County (Wis.) Medical Society.

This society was formed, November 7, at Oconto Falls, and constitution and by-laws as laid down by the American Medical Association for county societies were adopted. Dr. Herman F. Ohswaldt, Oconto Falls, was elected president and Dr. A. S. White, Gillet, secretary.

St. Joseph (Mo.) Medical Society.

This society, at its meeting, October 29, adopted a new constitution and by-laws. The dues have been fixed at \$4 a year, which includes the dues of the state society. It will be a branch of the Missouri State Medical Association.

Societies.

COMING MEETINGS.

Indian Territory Medical Association, Muskogee, Dec. 2-3, 1902.
Western Surgical and Gynecological Association, St. Joseph, Mo., Dec. 29, 1902.

The Tri-State Medical Association of West Virginia, Western Maryland and Pennsylvania will meet at Cumberland, Md., December 4. Dr. William Q. Skilling, Lonaconing, Md., is president.

Sanitary Convention of American Republics.—This convention will be held in Washington, D. C., beginning December 2, under the auspices of the governing board of the Bureau of American Republics.

Kanawha County (W. Va.) Medical Society.—At the annual meeting of this society, Dr. John T. Cotton was elected president; Dr. Harry H. Young, secretary, and Dr. Timothy L. Barber, treasurer, all of Charleston.

Sioux City (Iowa) Medical Association.—At the annual meeting of this body November 13, Dr. John P. Savage was re-elected president, Dr. John N. Warren elected vice-president, and Dr. Guy C. Rich, secretary and treasurer.

Congress of American Physicians and Surgeons.—The sixth meeting of the congress will be held in Washington, D. C., May 12, 13 and 14, 1903. Dr. William W. Keen, Philadelphia, is president, and Dr. William H. Carmalt, New Haven, Conn., secretary.

Sangamon County (Ill.) Medical Society.—At its annual meeting in Springfield, November 10, Dr. Albert L. Brittin, Athens, was elected president; Dr. B. Barret Griffith, Springfield, vice-president, and Dr. Percy L. Taylor, Springfield, secretary and treasurer.

Medical and Chirurgical Faculty of Maryland.—At the first session of the Section on Neurology and Psychiatry Dr. George J. Preston was elected president for the ensuing year. Dr. Henry M. Hurd read a paper on "The Future of the Care of the Insane in Maryland."

Hill County (Texas) Medical and Surgical Association.—At a meeting of this society in Hillsboro, November 13, Dr. James W. Miller, Hillsboro, was elected president, vice Dr. James J. Robert, resigned, and Dr. Andrew C. Saylor, Bynum, vice-president, succeeding Dr. James A. Adams.

Johns Hopkins Hospital Historical Club.—At the last meeting of this society Dr. Henry M. Hurd read a paper on "Thacher's Military Journal," and Dr. Eugene F. Cordell, a paper on "The Letters of Andrew Wiesenthal While a Student in London, 1786-1789." Dr. Cordell was elected president.

Inter-County (Wis.) Medical Society.—At the annual meeting of this society, held in Eau Claire, November 18, the

following officers were elected: President, Dr. E. Lewis Fletcher, Eau Claire; vice-presidents, Drs. William B. Hopkins, Cumberland, and Frank W. Epley, New Richmond, and secretary and treasurer, Dr. Caroline Hedger, Eau Claire.

Frederick County (Md.) Medical Society.—At the annual meeting of this society in Frederick, the following officers were elected: President, Dr. Franklin B. Smith, Frederick; vice-presidents, Drs. Charles C. Walker, Walkersville, and D. Edwin Stone, Mount Airy; secretary, Dr. Ira J. McCurdy, Frederick; treasurer, Dr. William C. Johnson, Frederick, and librarian, Elmer Fahrney.

California Northern District Medical Society.—At its twelfth annual meeting, held in Marysville, November 11, this society elected the following officers: President, Dr. Edward W. Hanlon, Marysville; vice-presidents, Drs. Harry W. Taggart, Stockton, Frank B. Sutcliffe, Sacramento, and Joseph T. Harris, Gridley; secretary, Dr. Elmer E. Stone, San Francisco, and treasurer, Dr. Oscar Stansbury, Chico.

Washington County (Md.) Medical Society.—This society, at its annual meeting in Hagerstown, November 12, elected the following officers: President, Dr. Japhtha E. Pitznogle, Hagerstown; vice-presidents, Drs. Christian R. Scheller, Hagerstown, and Charles D. Baker, Rohrer'sville; recording secretary, Dr. William B. Morrison, Hagerstown; corresponding secretary, Dr. James W. Humrichouse, Hagerstown, and treasurer, Dr. Hamilton K. Derry, Hagerstown.

Plant System Medical and Surgical Association.—The second annual meeting of the surgeons of the Plant System was held in Charleston, S. C., November 12 and 13. The following officers were elected: Dr. Roberts P. Izlar, Waycross, Ga., president; Drs. William D. Sutherland, High Springs, Fla., and Thomas S. Clay, Savannah, Ga., vice-presidents, and Dr. James H. Latimer, Waycross, Ga., secretary and treasurer. The association will meet next year in Jacksonville, Fla.

THE SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Fifteenth Annual Meeting, held in Cincinnati, Nov. 11-13, 1902.

Under the Presidency of Dr. W. E. B. Davis, Birmingham, Ala.

(Concluded from page 1340.)

McGraw's Method of Gastroenterostomy.

DR. SAMUEL LLOYD, New York, read a paper on his personal experience with this method. He reported 7 cases, all for cancer, except one, who had a gastric stricture due to adhesions. All recovered from the operation, but 4 died later from progress of the growth, without signs of obstruction. One died from involvement of the anastomotic opening in the cancerous growth, and consequent secondary closure of the new opening. The writer said that his experience showed the method to be efficacious and rapid. It had advantages over the button, in that the ligature, after it was tied, was extremely small and readily passed through the intestine, avoiding the danger of a heavy mass retained in an already diseased and ulcerated viscus, and that the opening in the stomach could be regulated to suit the case in hand.

The method was also applicable to the enteroenterostomies, which were made to avoid the vicious circle, and probably to cases of incomplete intestinal stenosis. It was not applicable to complete obstruction. Feeding could be commenced at the end of about forty-eight hours, and could be increased from day to day. He advocated in operating for pyloric obstruction, that from eight to ten ounces of peptonized milk and one ounce of whisky be introduced through a needle into the intestine below the point of the anastomosis during the operation.

The Surgery of the Lower Ureter.

DR. HUGH H. YOUNG, Baltimore, first described the topographic anatomy of the lower ureter.

The conditions requiring surgical treatment are as follows: Anomalies, as to number, location and condition; prolapse; ureteritis; calculus; neoplasm; valve formation; stricture; and fistula. The anomalous terminations into the uterus, vagina and vulva have been successfully transplanted into the bladder, but no similar operation is recorded in the male.

Prolapse of the ureter into the bladder is rare. Only 19 recorded cases have been found in the literature. Only 2

cases were operated on, and one died. The writer reported a case of his own.

Ureteritis in the lower ureter is not different from that in the upper, except that it is much more apt to lead to stenosis at the lower end. The changes observed on cystoscopic examination were discussed at length, with a report of the findings in several cases. Calculus impacted just above the bladder or in the intramural portion can generally be diagnosed at once by the cystoscopic appearance of the orifice; congestion, bulging, stenosis, with prolapse of the papilla generally being present. Likewise, tuberculosis can be recognized. In lesions of even lesser degree the orifice generally gives evidence as to which is the affected side.

Fistula of the ureter may be congenital or acquired, the latter generally occurring in the female after labor or pelvic operations. Anastomosis of the divided ureters or implantation into the bladder should be done. The ureteral papilla and its immediate neighborhood in the bladder is a favorite seat for vesical tumors.

Calculi which have passed the two points of constriction of the upper ureter just below the renal pelvis, and at the crossing of the iliac vessels, are most apt to lodge at the vesical juncture, or at the intravesical end, although they sometimes lodge in the intramural portion, or in the para-ischia bend. In the female, the intialigamentous portion of the ureter is a favorite location for calculi, and numerous cases are on record in which they have been removed through the vagina.

In the male, only 20 cases in which calculi impacted in the deeper pelvic ureter had been removed by operation were found in the literature, and 10 of these were intravesical or intramural, and were removed through the bladder. In the other 10 the site of impaction was above the bladder, in some part of the pelvic course of the ureter. In one of these the stone was removed by incision through the rectum, with fatal result. In another, the incision was made in the perineum, the rectum pushed back from the prostate, the ureter exposed at its vesical juncture and calculus extracted. Fenwick, the author of this operation, claims that this is the method of choice in the male. In the other 8 cases the calculi were removed through the iliac extraperitoneal route, 5 by European operators, and 3 in Baltimore. In the 2 cases of the writer, the calculus was situated in the justo-vesical portion of the ureter, but was very easily removed by the iliac extraperitoneal route. Finney had a similar case.

As to choice of route, it was clearly demonstrated that for all stones in the pelvic ureter, the iliac extraperitoneal route was the best, with the possible exception of the last three centimeters of the ureter in the female, where the close proximity of the vagina made that route an easy one. The difficulty of suturing the ureter here, the inability to examine the kidney above, or to treat stricture below, and the frequent persistence of fistula afterward might yet prove that the iliac route was the best for all cases above the bladder in the female also. Stricture of the ureter was rare, and only those cases requiring more than dilatation with ureter catheters were on record.

Indications for Extirpation of the Gall Bladder.

DR. MAURICE H. RICHARDSON, Boston, read a paper on this subject, in which he drew the following conclusions:

1. New growths and gangrene demand removal of the gall bladder whenever possible.

2. Contracted, thickened and inflamed gall bladders and all which do not permit of easy and efficient drainage should be extirpated, for in such cases the risks of drainage are as great as of extirpation.

3. Drainage is preferable in the dilated and infected or slightly thickened gall bladder containing stones and infected bile. This will, after drainage, become capable of fulfilling the functions again.

4. As a rule, drainage rather than extirpation is demanded in acute cholecystitis with severe constitutional symptoms, when the bladder is dilated or at least not contracted.

5. In chronic infections with dilatation and thickening, especially when a stone is impacted in the cystic duct, extirpation is preferable unless the stone can be dislodged backward into

the gall bladder, in which case drainage is, if not preferable, quite as advantageous as extirpation.

6. In simple gallstones, without visible evidence of infection, or of chronic changes incompatible with complete restoration of function, simple drainage is indicated.

7. In chronic pancreatitis, associated with gallstones or not, drainage through the gall bladder is indicated.

DR. ALEXANDER HUGH FERGUSON, Chicago, described a new method of anterior transplantation of the round ligaments for displacements of the uterus.

DR. GEORGE H. NOBLE, Atlanta, presented a paper on intramural extraperitoneal anchorage of the round ligaments for posterior displacements of the uterus, describing a new method for the relief of these displacements.

Fixation of the Round Ligaments.

DR. F. F. SIMPSON, Pittsburg, described a method of changing the course of the round ligaments from transverse to nearly an antero-posterior direction; in shortening the round ligaments, so that the weak part is left as slack, the strong part being used to control the movements of the uterus; finally, and especially in effecting these changes beneath or by puckering the parietal peritoneum, thus leaving no bands of adhesions, and no pockets which may strangulate an intestine.

Gas Bacillus Infection.

DR. ROBERT T. MORRIS, New York, reported three cases. The first was 46 years of age, on whom he operated for uterine myoma. The next day signs of infection appeared. On the third day he examined the abdominal wound and found it had healed by primary intention. The subcutaneous tissues on the right side of the abdomen were distended with gas, which was unassociated with tenderness, but on the fourth day caused great distress. He had no bacteriologic report. The patient died on the seventh day. In the second and third cases specimens submitted for examination showed pure cultures of what appeared to be the *Bacillus aerogenes capsulatus*. These two recovered:

DR. ALEXANDER H. FERGUSON detailed two cases. He said the *B. aerogenes capsulatus* had its habitat in the soil, and was not unlike *B. tetanus*, microscopically. It is not a pyogenic organism, as was proven by Welch and Nuttall, who made extensive experiments with it. It is the *B. emphysematosus* of the Germans. It finds its way into the body on greens, cabbage, etc., and one important point is to clean out the alimentary canal to get rid of it. Another important point is that it finds its way into the wound from the fingernails, hence the great importance of scrubbing the nails.

DR. J. WESLEY BOVÉE had encountered three cases following removal of the appendages for pus. One died. Autopsy showed the gas bacillus in various portions through the viscera, and particularly in the liver and skin.

Prolapse of the Uterus.

DR. CHARLES R. ROBINS, Richmond, Va., said the uterus is normally maintained in position by a combination of elements, and not by any one. These are integrity of the pelvic floor, making the pelvis a closed cavity, the uterus being of the same density as the other pelvic viscera, the position of anteversion and the tonicity of the abdominal walls. A departure from any one of these may cause prolapse, and where several are concerned, it is most frequent. Successful treatment can not depend on any one procedure, but it must meet all of the pathologic conditions present. Proper preliminary treatment is of the utmost importance. The operative treatment recommended consisted of amputation of the cervix, operation for cystocele, perineorrhaphy, and an operation for maintaining anteversion. This treatment not only cures prolapse, but restores function. If relapse occurs, Edebohl's panhysterokolpectomy seems to be the only operation for effecting a cure.

Diseases of the Ribs Following Typhoid Fever.

DR. J. SHELTON HORSLEY, El Paso, Texas, reported a man of 40 years, in whom disease of the left sixth and seventh costal cartilages, the anterior end of the sixth rib, and part of the sternum developed a few weeks after typhoid. The abscess

had been opened, and later the resulting sinus curetted before the patient came under Dr. Horsley's care. Then two extensive resections, involving a portion of the sixth rib, the costal cartilage of the sixth and seventh ribs and part of the sternum had to be performed before a complete cure was effected.

He called attention to five peculiarities that distinguish post-typhoid disease of the ribs from similar affections of other bones: 1. The marrow of the ribs is a particularly favorite seat for the typhoid bacilli. 2. The superficial position of the ribs and their continuous movement make a *locus minoris resistentiæ* more liable here. 3. Necrosis of the ribs is rare, of other bones, not. 4. Post-typhoid disease of the ribs invariably occurs in adults. 5. Thorough operative treatment is more difficult in the case of the ribs than of most other bones.

A table of 48 cases consisted of 41 men and 7 women. This is accounted for by men being more often subject to typhoid, and also by the fact that, owing to the mammary, the blood supply of the ribs is better in women.

Conservative treatment was advised in mild cases. If this should be unsuccessful, incision and curettage were advocated; and if, after a few weeks, the wound had not healed, extensive resection, going well into apparently healthy bone, should be practiced. Dr. Horsley also demonstrated a new holder for Gigli saws.

Renal Calculi.

DR. MACK ROGERS, Birmingham, Ala., confined himself to the diagnosis and treatment. He reported two cases and said the clinical history, pain, tenderness, swelling and condition of urine were the chief guides in diagnosis.

Endometritis.

DR. H. J. BOLDT, New York, said that the glandular, interstitial and mixed varieties form the basis of all variations of the disease. He outlined the differences between the varieties. The local treatment giving the promptest relief from bleeding in chronic endometritis is undoubtedly the judicious use of the curette. The operation should be done by one trained in gynecologic technic, because serious results frequently follow its improper employment. It is imperative that a careful bimanual examination be made previously, to determine whether or not a tubal swelling is present. Boldt had known tubal pregnancy and pyosalpinx to be ruptured by the operation. The same precautions as to cleanliness should be employed as in a major operation. In the writer's experience, about 60 per cent. were relieved from atypical bleeding for a variable period of time.

Good food, proper exercise, baths, douches, medicated or plain warm water are all important adjuvants to the treatment. After the endometritis has become chronic, it should be treated with intrauterine applications of one of the usual remedies. Dr. Boldt preferred a 10 per cent. solution of carbolic acid. Frequent intrauterine irrigations with large quantities of a mild antiseptic solution also give good results.

The Electric Caustic Clamp in the Treatment of Cancer of the Uterus.

DR. CHARLES P. NOBLE, Philadelphia, said the electric caustic clamp is a highly perfected and practicable instrument whereby it is entirely feasible to burn the attachments of the uterus and to leave not only a bloodless field, but one in which the lymphatics are sealed by a thorough cooking or roasting process. Hysterectomy thus performed possesses all the advantages of previous methods, and has in addition certain special advantages: More tissue outside of the uterus is removed or cooked than by the classical methods. All the connections of the uterus are either severed through tissue cooked in the bite of the caustic clamp, or severed with the electric caustic knife. The lymphatic vessels are sealed. Risk of implantation of cancer on the field of operation is greatly lessened. (An exception to the above statements must be noted, in that the attachments of the bladder to the uterus are severed in the usual way.) Much less blood is lost than is usual with the classical technic. A dry, bloodless field is left.

Dr. Noble said Dr. A. J. Downes, Philadelphia, adopted the

licable electric caustic clamp. Dr. Downes uses the method wherever there are pedicles to deal with, having abandoned the ligature in favor of the caustic clamp.

The technic was described in detail. [See description and illustrations in *THE JOURNAL*, July 12, 1902, p. 75.]

The essayist has operated five times by this method.

In closing, the essayist said that some years must elapse before the actual value of the clamp could be determined, but it was reasonable to expect a larger percentage of cures than the older methods, more especially in cancer of the cervix.

Other Papers Read.

The following papers, whose authors were present, were read by title, owing to the limited time at the disposal of the association: "A Case of Ovarian Fibroma," by Dr. H. A. Royster of Raleigh, N. C.; "Fracture of the Spine, with Report of Three Cases," by Dr. Howard J. Williams of Macon, Ga.; "Spinal Analgesia," by Dr. E. D. Martin of New Orleans, La.; "The Treatment of Posterior Uterine Displacements," by Dr. Edward McGuire of Richmond, Va., and "Dependent Drainage in Acute and Extensive Intra-Pelvic and Intra-Peritoneal Infection in Men by Incising the Perineum Separating the Rectum from the Prostate and Bladder, and Puncture of the Recto-Vesical Pouch of the Peritoneum," by Dr. Hugh M. Taylor of Richmond, Va.

BUFFALO ACADEMY OF MEDICINE.

Regular Meeting of the Medical Section, held Nov. 11, 1902.

Dr. Albert E. Woehnert in the Chair.

Medical Discoveries by Non-Medical Men.

DR. GEORGE M. GOULD of Philadelphia read a paper with this subject. He alluded to that grand sanitarian, Moses, and the effects of the Mosaic laws on the preservation of the Hebrew race. He quoted many paragraphs from the Bible to illustrate that medicine and hygiene must have been well known in biblical times, even bubonic plague and leprosy were well described. He spoke of the many therapeutic measures used even to-day referred to in the Talmud. We are just beginning to realize the truths of the Mosaic laws.

Reference was made to the Persians who regard the rivers as sacred and who do not bathe nor empty sewage into them.

He credited one Benjamin Jesty, a Gloucestershire farmer, with being the first to perform vaccination, preceding Edward Jenner by no fewer than twenty-two years. He quoted to show that the mosquito theory as to the cause of malaria was known many years, that many savage tribes used to anoint their bodies in order to protect themselves from the bite of the mosquito, and that even a report bearing on the relation of the mosquito to malarial fever was once sent to the naval department and no attention paid to it.

The relation of rats to bubonic plague is also a truth which was known from time immemorial. It was demonstrated that many times the observations of laymen precede medical discoveries and that on the observations of Zadik's, as well as the interpretation of characters like the mythical Sherlock Holmes will depend future discoveries as much as to the laboratory workers.

Care of Epileptics.

DR. WILLIAM P. SPRATLING, superintendent of Craig Epileptic Colony, Sonyea, N. Y., read a paper, illustrated by 56 stereopticon views, on how epileptics are cared for and treated at that institution. He spoke of two classes of colonies, (1) for selected cases, (2) for all epileptics save the insane. He prophesied that in the future every city of over 500,000 inhabitants will have its own colony for epileptics. In building an epileptic colony attention must be given to an epileptic's peculiarities, the difference of age, sex, social status, mental condition, etc.

Craig Colony for Epileptics represents the mixed type of colony, for its inhabitants comprise every variety of epileptic, from the epileptic of normal mind (5 per cent.) to the insane and idiotic. The epileptic must be suitably employed; 50 per cent. of them at the colony work: 25 per cent. do light house work.

It is necessary to educate the epileptic, and the earlier, therefore, an epileptic comes to the colony the better will the results be. There is a tendency for each recurring epileptic paroxysm to disorganize the brain and the memory is necessarily affected. Repetition is therefore a necessity in their education. The muscular education gives better results than education of the mind, so that manual training is employed to advantage at the colony.

The treatment is divided into (1) medicinal, (2) surgical, (3) dietetic and (4) moral. Nothing can be said of the medicinal treatment in a paper such as this. Every rational treatment is employed. Salt starvation (hypochlorization) is used with good results. Surgical operations are performed by the house staff at the colony. Brain surgery has not proven very successful. The ancestral history is carefully worked out in every case to ascertain an epileptic taint. Such cases are not operated on. Only when a focal lesion is present can an operation give good results.

Abdominal surgery is also performed with satisfactory results. Lately the eyes of many patients were examined for errors of refraction. Many patients refracted are much the better for the treatment. The dietetic treatment is carefully attended to. The epileptic must be recognized as a degenerate and discipline gently applied.

Dr. Spratling summarized his paper briefly as follows: 1. The colony treatment cures better than other forms of treatment. 2. It reduces the attacks. 3. It provides special education to make patients more helpful. 4. Promotes individual happiness. 5. Encourages research and provides for best treatment. 6. The segregation of such people has an economic value to the state, for it prevents handing down a defective progeny.

The paper was discussed by Drs. James W. Putnam, William O. Krauss and Allen O. Jones.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

Hemoptysis.

Hare, in *Med. News*, states that there is no doubt that of all the internal remedies for hemorrhage of the lungs, aconite is the best. If the patient is too much exsanguinated to use sedatives, place the head lower than the feet and apply an Esmarch bandage to the limbs. If the hemorrhage is just beginning, the following may be inhaled from an atomizer throwing a fine spray:

R. Liq. ferri subsulph. m. xx-xxx 130-2
Aque destil.̄iv 120

M. Sig.: To be sprayed and inhaled every few minutes; or:

R. Acidi tannici gr. xx 130
Glycerinīiii 8
Aq. destil. q. s. ad.....̄iii 90

M. Sig.: In atomizer; or:

R. Aluminis gr. vi 40
Aq. destil.̄iii 90

M. Sig.: In the atomizer. He states that if Monsel's solution does not stop the hemorrhage tannic acid will probably fail; but, more important, the two should not be used together, as they are incompatible, forming the tannate of iron.

Medical Treatment of Tuberculosis.

Dr. J. Shoup, in *Amer. Med.*, states, in the treatment of tuberculosis, that the following drugs should be selected:

1. Those drugs which promote metamorphosis, which results in healthy tissue construction. In this class he mentions iron, arsenic, strychnin, phosphorus and vegetable tonics.

2. Those drugs which are bactericidal in their action, and being eliminated by the lungs tend to attack the disease *in situ*. Creosote is taken as the type of this class given in large doses. However, he states that creosote given by inunction, inhalation, or enema has its drawbacks. When it is given by inunction

the odor becomes too disagreeable, and the irritation becomes unendurable; by inhalation it is too irritating and not so efficacious as the essential oils; by enema it soon becomes obnoxious to the patient, and by intratracheal injection it succeeds in checking the cough and partially deodorizing the sputum. He prefers guaiacol on account of its being less disagreeable to the patient. It is not so liable to cause gastric distress, and is quickly assimilated. Guaiacol carbonate is usually given, but guaiacol valerianate is an admirable remedy in nervous cases and is well borne. He has discontinued the use of ichtliol because of the disagreeable eructations and nausea of the patient. Its action is dependent on the sulphur it contains, and the author sees no reason why sulphur can not be given as such.

3. Those drugs which stimulate phagocytosis. This includes the serums and other medicinal agents as cinnamic acid, which may be given in combination with arsenic, as follows:

R. Acidi arsenosi gr. x 65
Potass. carb. gr. xvii 12
Acidi cannamiçīss 2
Boiled with aq. destil. q. s. ad.....̄i 30

Add:

Ext. opii (aqueous) gr. xxx 2
Vini gallicīss 15
Aq. destil.̄iii 60

M. Sig.: Begin with three drops after lunch and after dinner and increase to twenty drops.

Tubercular Laryngitis.

G. L. Richards, in *Internat. Jour. of Surgery*, recommends the following formulæ in the form of insufflations in the treatment of tubercular laryngitis:

R. Morphina sulph. gr. v 30
Iodoformīiii 12

M. Sig.: A small amount to be insufflated by means of a powder blower; or:

R. Morphin. sulph. gr. 1/30 1002
Hydrarg. chloridi mit. gr. xx 130
Sacch. lactis gr. xl 265
Bismuthi subnit. gr. xl 265

M. Sig.: To be used as an insufflation. He states that intratracheal injection of guaiacol, menthol and orthoform, as in the following formulæ, frequently afford relief and possibly retard the progress of the disease:

R. Menthol. gr. xxx-̄iiss 210
Ol. amygd. dulcis.̄i 30
Vitelli ovīvi 24
Orthoformīiii 12
Aque destil.̄iii 90

M. Ft. emulsio. Sig.: To be used on a swab or in an intratracheal syringe, preferably the latter; or:

R. Camphoræ
Menthol.
Guaiacol, aa gr. xlvi 320
Olei olivæ q. s. ad.....̄ii 60

M. Sig.: To be introduced with the intratracheal syringe during inspiration.

Treatment of Epididymitis.

Bandoy, according to an abstract in *N. Y. Med. Jour.*, recommends for the local treatment of epididymitis continued moist medication with a sterilized solution of sodium chlorate. The use of ice has the objection of causing induration that may lead to obliteration of the vas deferens. When the acute initial pain has been subdued, sitz baths repeated four or five times daily, lasting from fifteen to twenty minutes at least, and finally for forty-five minutes, should be employed, continuing also the use of moist compresses. As soon as the sensitiveness has been diminished so as to allow of light massage, frictions with resolvent ointments can be made, twice daily after the bath for fifteen minutes:

R. Tinct. iodi gtt. xv 1
Pot. iodidi gr. xxx 2
Petrolatīv 20

M. Sig.: Apply locally twice a day.

Internally one gram (gr. xv) of potassium iodid should be given daily. By following this plan accurately one obtains

more surely than by any other method, a satisfactory retrogression of the inflammatory infiltration and complete restoration to the normal condition.

Bronchitis.

According to Musser in *Nothnagel's Encyc. of Med.*, bronchitis frequently begins with an acute cold in the head, coryza, and perhaps pharyngitis, with symptoms of general malaise, fever and muscular pain. There are also cases with laryngitis rapidly extending to the bronchi and others beginning primarily in the bronchi. In the first class, if there is much headache and frontal pain, he recommends the following:

R. Camphoræ	gr. i	106
Ext. belladonnæ	gr. i-ss	106-09
Quininæ sulph.	gr. i-ii	106-12
Morph. sulph.	gr. 1/40	1005

M. Fiat. capsula No. i. Sig.: One such capsule every half hour for four doses. Then one every three hours.

If the patient should suffer from myalgia, chest oppression, tight cough, one of the following combinations is recommended:

R. Quininæ sulph.	gr. i-ii	106-12
Pulv. opii et ipecac.	gr. i	106
Acetanilidi	gr. i	106

M. Ft. capsula No. i. Sig.: Take two such capsules at once, two in two hours, then one every three hours; or:

R. Mist. potassii cit.	℥iv	120
-----------------------------	-----	-----

Sig.: One tablespoonful every two hours; or:

R. Potassii iodidi	gr. xlv	3
Vini ipecacuanhæ	℥iii	8
Mist. glycyrrhizæ co. q. s. ad.	℥iii	90

M. Sig.: One teaspoonful every two or three hours.

If the cough is harassing, 1/30 to 1/12 (.002-.005) grain of heroin may be added to the dose in any combination.

The following serves well to relieve the cough and oppression:

R. Syr. ipecac.		
Syr. sanguinarie		
Syr. scillæ, aa.	℥iii	8
Syr. pruni virg. q. s. ad.	℥iii	60

M. Sig.: One half to one teaspoonful every two or three hours.

In the later stages ammonium chlorid, terpin hydrate, terebene and tar preparations are recommended:

R. Ammon. chloridi	℥i	4
Terpin. hydratis	℥i	4
Pulv. opii et ipecac.	gr. xxiv	165

M. Ft. cap. No. xxiv. Sig.: One or two, according to the age, every two or three hours.

In the above, if the cough is easy and the expectoration free the opiate may be withheld.

The following is of service to meet the general indications in bronchitis:

R. Ammon. chloridi	℥i	4
Vini picis liq.	℥i-ss	6
Mist. glycyrrhizæ co.	℥i-ss	45

M. Sig.: Two teaspoonfuls every two or three hours.

The author very justly adds that stimulants, as strychnin, keep up blood pressure and arterial congestion and hence tend to aggravate the bronchitis present. However, should venous hyperemia exist their use is justifiable.

A New Method of Extracting Foreign Bodies from the Ear.

There is no more delicate and even difficult task, so states the *Med. Press*, than the extraction of a foreign body from the external auditory canal. Irrigation often fails to bring it away, and in certain cases adds to the difficulty by causing the object, a pea for instance, to swell and become more firmly impacted. The employment of instruments is very painful and requires considerable dexterity, besides supposing an armamentarium specially designed for the purpose, which few general practitioners possess. The recommendation is made of a piece of soft rubber tube, the length of a cigarette and of the proper size, to be introduced into the ear. The end of the tube is dipped in paraffin and pushed into the canal until it comes in contact with the foreign body, whereon the operator, applying his mouth to the free end, aspirates forcibly, at the

same time throwing back his head. Except in cases of angular bodies of irregular contour this method is usually attended by success, the body coming away with the tube.

Medicolegal.

Three Thousand Dollars for Fracture of Femur.—The Supreme Court of Iowa holds, in the personal injury case of Beringer vs. Dubuque Street Railway Company, that, in view of the character of the injury—the head or neck of the femur being fractured—and the evident pain and suffering caused thereby, a verdict for \$3000 was not excessive.

Physician Must Show Prior Appropriation for Services.—The Nebraska case of De Wolf vs. Village of Bennett was brought by a physician to recover for services rendered in taking charge of a smallpox patient. He alleged in his petition that he was duly authorized by the State Board of Health to practice medicine and surgery in the state and had filed his certificate; that the village was a duly organized municipal corporation; that it was authorized by statute to provide pest-houses, to prevent the introduction and spread of contagious diseases, and to make contracts and incur expenses for that purpose; that on or about a given date a certain party was afflicted with smallpox, and the other residents of the village were in danger of contracting the disease; that the village, acting by and through its trustees, established a pesthouse, and requested him to remove the party thereto and to take charge of and treat the case, and prevent the spread of the disease, for all of which, through its trustees, it agreed to pay him, in pursuance of which he rendered the services sued for, which were accepted and received by the village, and by the trustees without objection; that he made the fair and reasonable charge of \$104 therefor, presenting his account to the village, and filing same with its board of trustees, demanding payment, which was refused. To this petition a general demurrer was interposed, the village contending that it was necessary for the physician to plead the contract, and that the proper preliminary proceedings had been taken by the village board, showing that an appropriation had been made, because, without such appropriation, the village had no authority to make contracts or create liabilities like that involved in this case. The demurrer was sustained, and the Supreme Court of Nebraska holds that this was proper, the claim on which the case rested being one for which a prior appropriation was essential.

Libel of Physician by Calling Him a "Quack."—A newspaper said that a certain candidate for office might as well give up the fight. It had supposed that he had at least a fighting chance, if not an absolutely sure thing. "But," it continued, "here comes 'Doctor' Ralph Elmergreen, the spick and span practitioner, who says that it's all off, and that all the powers of hades can't prevent Sam's re-election. The burden of the doctor's refrain is vindication—for Sammy. It appears that some untruthful Democrat misquoted Sam's Hartford speech, particularly that portion of it concerning the regulation of trusts. We do not know what Barney said about trusts; neither do we care. Sufficient be it that we do not look to a quack to set us right in the matter. . . ." An action for libel followed. Evidence was produced on behalf of the party sued, who was the editor, publisher and proprietor of the paper, to the effect that he knew that the party suing was a physician and surgeon, but that he had no intention of injuring him in his professional capacity. There was also evidence introduced on behalf of the publisher in regard to the various dictionary definitions of the word "quack." The result was a verdict and judgment for the publisher. But this last is reversed by the Supreme Court of Wisconsin, and a new trial ordered. It says, *Elmergreen vs. Horn*, that it was correctly ruled that to speak of a physician in his professional capacity as a "quack" is to call him a mere pretender, a person boasting of attainments he does not possess, and is libelous as a matter of law. It was further correctly ruled that in a case of this kind if there are conflicting reasonable inferences as to whether the alleged libelous language should be understood in

a libelous sense, the right of the matter must be determined by a jury. The trial judge concluded that there was such a conflict in this case, and refused to give instructions to the jury in effect, taking away from it the question of whether the article complained of was libelous *per se*, or in and of itself; and that is what the Supreme Court holds was reversible error. Candor, it declares, compels it to say that it can not discover any doubt, approaching the boundaries of reason, as to whether the term "quack" was used with reference to the party suing in his capacity as a physician and surgeon. Taking the language all together, with the same certainty as it referred to him as doctor, it referred to him as a quack doctor, as a mere pretender in his profession, a person not possessing the skill of a reputable practitioner of medicine, though assuming to have such skill. Note, it says, for one thing, the significance of the inclosure of the word "Doctor" in quotation marks, indicating that the writer wished to dignify him by the title of doctor in no other sense than that he was so called or held himself out to the world as such. And finally the Supreme Court says that it would be a waste of time to multiply words in demonstrating that the only meaning suggested by reading the article in question was that the party suing was referred to therein as a quack doctor. If the learned circuit judge had not considered the matter doubtful, the court would feel that one could not seriously present it for consideration from the standpoint of the party sued. That the judge erred in submitting the primary question of the latter's liability to the jury, the court regards so clear that it is not justified in saying more.

Venereal Disease as Evidence of Rape.—The Supreme Court of Iowa says, in the case of *State vs. Height*, that a prosecution for rape on a child 10 years of age, the evidence tended to show that the latter did not make complaint until about 11 days after the alleged outrage, and then, on examination by physicians, was found to have venereal disease. To show that at the time of the alleged intercourse the accused was afflicted with the same disease, which he might have communicated to the child, there were called as witnesses certain physicians who had examined the private parts of the accused while he was confined in jail under arrest for the crime charged, and who found that he then had, or had recently had, the disease in question. For the accused it was contended that this physical examination of him was made against his protest, and, further, that the testimony of these physicians was with reference to a privileged communication. But the court suggests that it was enough to say in answer to this last contention that the physicians were not called by the accused, nor did he, even if he submitted to the examination, do so with the idea that the physicians making it were acting as his physicians. The objection to the testimony that it disclosed a privileged communication was therefore not well taken. Again, it was urged that the testimony related to a confession by the accused which was not voluntary, and that the evidence should have been excluded for that reason. The court replies that the accused made no confession of guilt, nor admission that he was afflicted with the disease for which he was examined, and that it has been well settled by decisions without conflict, that, even though a confession be involuntarily made, inculcating facts discovered by means thereof may be established against the accused. Consequently, there was nothing in the rule excluding involuntary confessions to prevent the physicians who made the examination of the person of the accused from testifying to his condition with reference to having venereal disease. However, inasmuch as the examination by physicians was made under the direction of the prosecuting attorney, and was at first resisted by the accused, who finally consented thereto, if at all, only after he had been told by one of the officers who made the arrest, and who was present, acting under the direction of the county attorney, and in his presence, that the state had the right to require such an examination to be made, and that the accused must submit to it, the court holds that this was amply sufficient to indicate legal duress, and that evidence secured by such duress, and which could not have been secured otherwise, was inadmissible over the objection of the accused. In other words, it holds that the officers acted unlawfully in com-

evidence with reference to information secured thereby should have been excluded on his objection. It takes this position, notwithstanding there is no such provision in the Iowa constitution as in some others to the effect that the accused in a criminal prosecution shall not be compelled to be a witness against himself. The court further holds that if on a retrial there should be competent evidence that the accused had venereal disease at the time of the connection with the prosecutrix, evidence—if any were brought forward—of her having had sexual connection with others near the same time should be admitted to show that the disease might have been contracted by her from other sources.

1. Eczematoid Dermatitis.—Engman enumerates the basic and principal results of his investigations in the following:

1. The contents of the initial vesicles, serous and seropurulent discharge, under surface of crusts and scrapings from freshly denuded surface of eczematoid skin, produce, when inoculated into artificial culture media, pure cultures of the staphylococcus, yellow or white or both. These cocci sometimes vary slightly in the peculiarity of their growth, but are certainly the staphylococcus of the ordinary types.

2. When the apparently healthy skin of a person suffering from an eczematoid dermatitis is slightly irritated, after being rendered sterile by the usual means, and then inoculated with the discharge from the eczematoid surface, there appears thereon a condition similar in its flora and symptoms to the one from which the discharge was taken. Inoculation experiments from individual to individual have not been encouraging, due most probably to the patient's unwillingness to properly submit or the reaction of the foreign soil.

3. Inoculations upon individuals from artificial cultures were also not encouraging. The organism must undergo some change in its chemotactic character in artificial media, as inoculations from it produce impetigo or purely impetiginous lesions which quickly heal; or if the lesion takes on an eczematoid character it heals too rapidly to be of much experimental value.

4. The suppurative conditions with which eczematoid dermatitis is often associated always contain staphylococci.

5. The association with suppurative conditions; history of apparent infection and infection; exciting factor of traumatism and infection; findings enumerated, all indicate and confirm phylogenetic origin of this dermatitis.

2. Ear Disease.—Amberg describes the anatomy of the ear, with illustrations, and repeats the classic indications of Schultze in regard to the early mastoid operations. He remarks that when interference is not directly based on the vital indications, the timely paracentesis may frequently make a mastoid operation unnecessary, and that a timely mastoid operation may save the patient from undergoing a radical operation or operations for complications, which are not always successful.

4. Anesthesia.—The conclusions of Eisendrath's article are:

1. Chloroform has a narrower zone of safety than ether. Its toxic effects are, as a rule, manifest at the time of administration. Ether is the cause of death in many cases through renal or pulmonary complications from hours to days after the anesthesia. The late deaths due to chloroform are so rare as to render this factor practically of no importance. Chloroform is a more dangerous anesthetic than ether and must be watched far more carefully.

2. Chloroform kills more frequently through primary cardiac than respiratory syncope, and the anesthetizer must watch constantly the decrease in volume and rapidity of the pulse, indicating the fall of blood-pressure, and a slowing of the more shallow respiration. Chloroform syncope can be avoided by keeping the head low, if possible turned to one side, keeping the jaw forward, watching the pulse, respiration and pupil, keeping the patient's mind quiet and keeping the chloroform well diluted with air.

3. Ether rarely causes death through its immediate, but more frequently through its after-effects, such as pneumonia and uremia. These complications may be avoided by keeping the head lower than the level of the body, turned to one side, and not giving the ether in too concentrated a form; also by not keeping the patient on his back too long, and by relieving postoperative tympanites as soon as possible. The contraindications to the use of chloroform are myocarditis, pericardial adhesions and noncompensated valvular disease. In all other forms of heart disease it may be given. It should not be given when the blood pressure is low or in status thymicus, or when a prolonged anesthesia is necessary.

4. The pulmonary complications are relatively more frequent with local anesthesia than if a general anesthetic is given. They may be due to aspiration of mucus or food, or due to hypostasis and to embolism. The latter is far more frequent than is ordinarily thought. Avoid these by exposing patients as little as possible. Use heated operating tables, avoiding recumbent position and tympany.

5. Avoid renal complications by careful examination of the urine before anesthesia.

6. Begin process of resuscitation immediately and systematically: Artificial respiration, the method of König-Maas, or massage of the heart, rhythmic traction of the tongue, method of Prus, or direct exposure of the heart and intravenous salt transfusion. I prefer to begin with massage of the heart and rhythmic traction of the tongue (16 to 18 times a minute).

5. Pernicious Anemia.—According to Adler, who reports and remarks on cases of pernicious anemia, we have to deal in this condition with a toxic process, the stress of the action of the poison or poisons being exerted on the blood and cord. The resulting hemolysis is confined chiefly to the portal area. The gastric atrophy is regarded by almost all authorities as a primary condition, and presents conditions favorable for elaboration and absorption of the toxins, acting in other ways as a predisposing cause. We are to look on the anemia of pernicious anemia as only a symptom, but from the marked alteration which the blood undergoes, and the vital effects thereof, it is the most important symptom of the disease to which our therapy for the present must be directed.

6. Tuberculosis.—Lyle reviews his experience in a municipal hospital and notes particularly the necessity of following up the treatment, and the almost constant association of pleurisy of the dry type, the predominance of intemperance and syphilis in the histories, the importance of family history and of contagion, and the unreliability of statements as to the duration of the disease. About 90 per cent. of the cases were of the fibrocaceous variety; 9 per cent. of the fibroid form of the disease, while acute miliary tuberculosis of the lungs and lobar caseous pneumonia were rare. The majority of persons under twenty have a more or less extensive involvement of the lymphatic glands, and general tuberculosis is more likely to occur in the young. Next to the lymphatics we find the frequency of tuberculous complications of other organs in the

following order: Larynx, intestines, pharynx, joints, kidneys, peritoneum, bladder, meninges, testicles. Indigestion and faulty circulation due to heart weakness are almost constant. He thinks the bacillus is being relegated to a far less prominent position than formerly, and we should devote our efforts to remedying the physical and mental depreciation due to inheritance. His creed would be: "I believe in the inherent ability of the cells of the body to maintain the tissues in a healthful condition, both by destroying diseased germs and neutralizing the products of their activity. In order that this be done their potency must be maintained at the highest standard." For this purpose we must have pure air, sunshine, intelligently selected dietary, abstinence from alcohol, tobacco, etc. Blood examinations are sometimes of interest, but never of pronounced diagnostic value; the results of urinary examination are only of general significance. He believes in the tuberculin test as permissible if lack of time does not permit delay. There are no specifics. The α -ray is only of value in the diagnosis. He has not found it of value in locating cavities. Its use for therapeutic purposes was disappointing in fifteen cases thoroughly tested, though its effect in relieving pleuritic pains was marked. He concludes that we should remember that in temporarily relieving the patient of a symptom we may use drugs that have a bad general effect.

9 and 10. **Climatology of California.**—McAdie, in this article, sums up the advantages of the California climate. Sanborn takes up the same subject, limiting his remarks to the region beginning at the mouth of Cajohn Pass and encircling the East San Bernardino valley, taking in Riverside just across the divide, and other localities near at hand. This excludes the coast climate, but gives that of almost every other variety from that of the desert below the sea level to an altitude of about 10,000 feet. He remarks especially on temperature changes and notices the nervous troubles which seem to prevail, part of which he thinks are due to the constant eye-strain from perpetual sunshine, but perhaps the most important factor is nostalgia. He thinks, as the country develops, conditions for recreation and contentment multiply, and in the near future nervous troubles will be less and less prevalent.

11. **The Climate of Maine.**—Hinsdale remarks on the health conditions and on the decrease of consumption in that state during the last ten years, which has amounted to 15 or 20 per cent.

12. **Cervical Lacerations.**—The medical treatment of cervical lacerations is advocated by Bushong, who thinks that operations may be overdone. He finds Monsel's solution the best medicinal application in promoting absorption and removal of cicatricial tissue underlying mucous membrane. He uses the tampon, applied after local treatment, and considers it an important factor in the management of the cases. When the mucous membrane is broken or eroded he finds the best results in healing erosions come from a combination of pure tincture of iodine and beechwood creosote, using it before applying Monsel's solution for its action on the deeper structures. The frequency of these applications must be carefully considered. If the patient is very sensitive, once a week is sufficient, suspending treatment about three days before expected menstruation, and not resuming it until the fourth day after cessation of the flow. In very bad cases it is wise to make a visit every five days, and to apply the iodine at every alternate visit, using only the iodine and creosote at the others. If there is too much irritation the condition will be relieved by leaving out Monsel's solution for a few treatments, resuming it when tenderness has passed. He reports cases showing the benefits to the cervix from local treatment.

17. **Pleural Endothelioma.**—Delafield reports four cases of primary endothelioma. He remarks that it is generally agreed that the primary new growths of the pleura originate in the lymphatics and are endothelial in their nature. The symptoms can hardly be distinguished in the beginning from ordinary pleurisy with effusion. Only the bloody serum and low temperature are suspicious, but as the weeks follow each other the loss of flesh and strength and the appearance of the patient suggest malignancy.

18. **Radiotherapy.**—Allen has treated a number of cases of cancer and other cutaneous affections with the α -rays, and finds a decided value in the treatment. Out of 50 cases of cancer 20 were discharged as clinically cured, 4 as improved, 10 were still under treatment and improving, and only 3 cases were discharged as unimproved, 2 were referred for surgical operations and 5 ended fatally. Eleven cases were as hopeless at the beginning of treatment as all who have to do with breast and uterine cases and cancer of the rectum know. He thinks he has observed a tendency of the tubes to produce dermatitis irrespective of their vacuum, or of any idiosyncrasy on the part of the patient. He does not believe that a surgical operation should necessarily precede the α -ray treatment. He has also used it in a great variety of skin affections, including lupus, psoriasis, eczema, acne, lupus erythematosus, xeroderma pigmentosum, favus, ringworm, leprosy, lichen planus, etc., and has secured in many cases better and quicker results than by the older methods alone, though he does not rely on it solely. In Hodgkin's disease and internal sarcoma, though he has no cure to report, he has had some gratifying improvements.

20.—See abstract in THE JOURNAL of October 25, p. 1066.

21.—See abstract in THE JOURNAL of October 4, p. 854.

22. **Epilepsy.**—Thomson concludes his article in this issue. After first noticing the necessity of looking after the reflex centers and the coexistence of focal cortical disorders, he mentions cases where the reflex center was in the nose, but states that the greatest area is in the throat and pharynx. The gastrointestinal tract is also a well-known seat of afferent irritation. The mechanism of the action of the bromids is partly by their reduction of the peripheral sensibility in the pharynx. Other remedies that he mentions are coal-tar sedatives, especially antipyrin, which increases the specific action of the bromids, also chloral. The great aim in the treatment of epilepsy is, however, in prophylaxis, and it is in the gastrointestinal tract that the commonest autoinfection is to be found. Intestinal antiseptics are usually required earlier or later in the treatment. Imperfect kidney elimination is also a cause. He especially notes the value of life in the open air as a remedial measure. He gives a high estimate of the curability of epilepsy, and thinks that the prognosis for complete cure in average cases is about 70 per cent. The reason why the actual cures do not reach this figure is because the patients will not follow out the treatment; they grow careless after more or less prolonged freedom from attacks. The incurable patients are those in whom an intracranial cause of afferent derangement has been operative from early life, and those in whom the epileptic habit has been engrafted on a poor constitution from youth, though many of these recover.

23. **Ringworm.**—The infection from ringworm cases is studied by Newborn, who sums up in the following: "1, that differences of soil modify the clinical picture of a skin ringworm as well as the microscopic appearance of the fungus; 2, that in the fluid of a herpetic vesicle the mycelium of a microsporion may produce external grape-like spores; 3, that the yellow and brownish bands and the tangential fringe on beer-wort agar can be used to identify the source of infection in ringworm of the cat."

25. **X-Rays.**—From his experience in the treatment of many cases, Rudis-Jicinsky lays down the following general rules: 1. Know the capacity of the apparatus, remembering that the so-called α -ray burns are produced with a static machine as well as a coil. Learn every point in regard to the individuality of the tube. For superficial growths use a "soft" or "soft medium" tube with a spark gap of two inches; for internal growths a "high vacuum" tube with a spark gap of four inches. Try each tube before each application. 2. Thoroughly examine the case. Know the patient well. Protect the hair and eyes and the healthy tissue, if necessary, with lead and rubber; the latter to prevent shock by induction. Ray all the suspicious parts in as large an area as possible. 3. The length of exposure depends not so much on the time during which the tube

is in action, as on the actual time of best x-ray production, tested occasionally by the fluoroscope. The exposures are to be made according to each individual case, five minutes at first, and after a week, for ten minutes. If, two weeks after the first exposure, no reaction has been shown, the patient has no idiosyncrasy and may be irradiated every second or third day, and finally every day until intense reaction shows itself. The distance at the first application should be six inches, later less than that. If itching of the skin follows, stop the treatment for a while. 4. If it is unwise to treat the whole diseased surface at once, begin at the edges. If there are a few isolated nodules after the general surface of the growth begins to look better, a change of treatment is needed, and the nodules have to be attacked more vigorously. 5. Watch the progress and the results of the treatment carefully, and see whether the case is one for operation with the treatment or not. 6. Protect yourself and be prepared for all occasions, having in your office or laboratory a sign, perhaps, like this: "X-ray examinations and treatments at the risk of the patient. All possible and professional skill used."

27. Post-Operative Abdominal Cases.—Deaver and Müller report some methods used in the German Hospital at Philadelphia. They find shock unimportant as a sequel in case the operation has been performed rapidly and thoroughly. Stimulants such as strychnia, atropin, whisky, and camphorated oil hypodermically, with hot water bags and the use of hot saline solution by the bowel cause rapid reaction. Hypodermoclysis is not used as it is too cumbersome and slow. Where shock is due to hemorrhage the patient almost invariably recovers under this treatment, but this is not the case where there is septic absorption, which gives the same symptoms. In clean cases the patient is kept on the back for twelve to forty-eight hours, the time depending on the length of the incision. When the gauze drain has been employed the patient is slowly turned by supporting pillows to one side at the end of seventy-two hours. With glass drainage no change is permitted, except alternate raising of the hips on pillows. In clean cases without drainage asafetida suppositories are given every three hours, and unless the pulse demands strychnia, no medication is used. Water is not given until eighteen hours or longer if nausea persists, though the mouth may be washed out and the lips moistened. Backache is often an annoying and painful sequel. Very hot water bags or a cold water bag may be tried, but nothing usually gives relief except change of posture. This is preferable to morphin. In ten or twelve hours after the operation flatus will be passed. If it does not pass for eighteen hours an enema of milk of asafetida may be given, 60 c.c., in an equal quantity of warm water. It is a mistake to give morphin in these conditions. If the asafetida enema fails one or two ice bags on the abdomen and a high enema of turpentine, glycerin and magnesium sulphate in the proportion of one, two and three, is employed. On the third or fourth day after the operation the bowels are moved with a plain enema or with a glass of citrate of magnesia. Twenty-four hours after operation they begin giving nourishment, first milk and lime water, 5 to 10 c.c. of each every hour, rapidly increasing the quantity if well borne. On the second day chicken broth, beef tea and junket may be given with the milk. On the third, wine-jelly and gruel may be added, and from then on the diet is gradually increased until by the seventh day the patient is getting about 300 c.c. of nourishment. If the temperature is high after the bowels have moved, they look for stitch abscesses, and usually apply flaxseed poultices. In clean cases the wound is rarely dressed until the eighth day, when the stitches are removed. In drainage cases the glass is removed in two to four days, depending on the discharge; the gauze is removed from the sixth to the twelfth day, depending on the force necessary to loosen it. The rubber drain is shortened from day to day as the wound granulates up from the bottom. In removing the gauze drain, boric acid should be used for irrigation as the adhesions may not be perfectly formed and a bichlorid or carbolic solution might arouse a peritonitis. They call especial attention to the use of gastric lavage for the nausea and vomiting. The stomach usually recovers its tone in a few hours, but in other cases this method may be required. They have

never seen any serious depression or hematemesis following the use of the stomach tube, nor have they ever introduced the tube into the trachea, and think it could not happen with ordinary care. Where there is paresis of the bowel lavage is remarkably beneficial, as also in cases of cholelithiasis with gastric disturbance and especially in those cases re-operated on for gastro-hepatic adhesions. It is their routine practice to wash out the stomachs of such patients every six hours for the first twenty-four hours after the operation. Purgation is the sheet anchor in the treatment of peritonitis, but it can not be used in case of vomiting, and lavage sometimes seems to work well. They wash out early and introduce 30 to 60 gm. of Glauber's or Epsom salts, sometimes adding 30 c.c. of whisky or a pre-digested food.

20. The Diet in Typhoid.—Robertson advocates a freer diet in typhoid, believing that it will diminish the number of deaths from asthenia and intercurrent affections and lessen the increased liability to perforation.

30. Foreign Bodies in the Vermiform Appendix.—Bell reports two cases, one in which there was a pin and in the other a gallstone producing the trouble in the appendix. He thinks while it is unquestionable that foreign bodies rarely cause appendicitis, it is worth while to put these cases on record.

34. Nail Disease.—Eczema produces the most frequent examples of nail disease, furnishing 107 out of 485 cases on which White's paper is based. It is due to the same causes as bring about an eczema of the skin, and it causes total loss of the nail. Unless the matrix is affected in trauma or felon, the results on the nail are unimportant. Paronychia comes third in importance, providing 68 cases. Psoriasis is almost an equally common disturber of nail equilibrium, while involvement of the nails in cases of cutaneous psoriasis is much commoner than is the rule in eczema. The prognosis, he thinks, is generally good, but he has seen cases where the nails did not return again. There were 62 cases of nail implication in dermatitis of the hands and fingers directly attributable to some noxious occupation or chance poisoning of the skin. The commonest symptom is koilonychia, which appeared in about 40 per cent. Syphilis of the nail is not a common condition, found in only about 5 per cent. of his cases. It occurs both in the primary and secondary forms. Tinea trichophytina is a very rare condition, usually caused by the megalosporon; tinea favosa is a little more common. The clinical appearances of the two diseases are quite similar. Tinea favosa may be contracted from domestic animals. Russian Jews seem to be specially liable to it.

44.—See abstract in THE JOURNAL of October 25, p. 1065.

49.—See abstract in THE JOURNAL of October 25, p. 1066.

54.—This article has appeared elsewhere. See THE JOURNAL of November 8, title 142, p. 1210.

63. Morphin.—The indiscriminate use of morphin by physicians is deprecated by Crothers, who calls attention to the possibility of its producing narcomania and the danger, although the physician may conceal from the patient what drug he is taking, of its being revealed to him later in the case of change of doctors. Proprietary drugs given for the purpose of controlling pain also contain dangerous and uncertain narcotics and should be avoided. Many obscure diseases may be traced to reckless medication of this kind.

64. Alcohol.—Cushing pleads for alcohol a place in therapeutics as a narcotic and to a less extent as a stomachic, and in certain conditions as a food. He does not deny the fact that it has drawbacks, like every other drug, but we should not be guided entirely by consideration of any one of its properties, but estimate the total of its effects, good and evil, as regards the special condition.

65. Methyl Alcohol.—The action of methyl alcohol is reviewed by Hunt, who gives the results of his own experiments and the experience of others with this agent. Even when free from impurities it is dangerous and it is totally unfit as a

substitute for grain alcohol in any preparation which is to be taken internally, especially those to be given for any length of time.

72.—This article has appeared elsewhere. See *THE JOURNAL* of October 25, §36, p. 1072. See also editorial, November 22, p. 1327.

75. **The Blood in Pregnancy.**—The conclusions reached by Pray from examination of the blood in pregnancy and the puerperium are given by him in the following: "1. Where blood generation fails to keep pace with the increased vascular area, a serious dilution of the blood takes place. 2. In the majority of cases this is not serious, and can be overcome by simple hygienic measures—fresh air, good food and the overcoming of constipation. Cases in which the vitality is overtaxed by the increased demand for nutrition may call for iron or other hematinic treatment. 3. The regeneration of the blood is partly effected by the lessening of the vascular area after labor and subsequent transudation of fluids of the blood into the tissues. 4. The leucocytosis is due to increased action of enlarged lymph glands of the pelvis, and in part to increased metabolism, which causes a somewhat toxic condition. Its decrease is caused by the lochial discharge. Its persistence is accounted for by the fact that the involution of the hypertrophied pelvic organs and breasts is accomplished in a great measure by the leucocytes. 5. A study of the blood of a woman delivered by the Cesarean operation shows the same general behavior of the blood constituents as does that of women after normal labors."

77.—See abstract in *THE JOURNAL*, xxxviii, p. 1667.

79. Ventrofixation and Ventrosuspension of the Uterus.

—After discussing the indications according to which these operations are performed, Kreutzmann expresses the view that they are only relative and that as surgical procedures these operations create an unphysiologic condition. The remote consequences are sometimes disastrous to the health and life of the subject, and even grave disturbance of the normal progress of gestation is occasionally observed. These are not indispensable operations. While it may be said sometimes that it is right to propose a surgical rectification of a backward displaced uterus, fixed or movable, it should be devoid of danger to the life and health of the patient, immediate or remote. In women of childbearing age it should be free from the danger of interfering in the least with the normal progress of pregnancy and delivery. Ventrofixation and ventrosuspension as usually performed are not thus devoid of danger. In vaginal fixation (in nonparous women) and in shortening the round ligaments (by either vaginal, intra-abdominal or inguinal route) we have at our disposal operations which, if properly selected, combine efficiency with absolute freedom from danger.

86. **Collodium After Nose Operations.**—Pischel finds collodium a satisfactory local application in the after-treatment of nose operations. When through with the operation (removal of hypertrophy on lower turbinal, for example), he touches the wound several times with adrenalin to stop the bleeding, and then drops collodium on the wound while an assistant blows compressed air into the nose to accelerate evaporation. The collodium forms a firm white membrane, which protects the wound against infection and prevents secondary hemorrhages. He has used it in thirty-one cases and has not had one secondary hemorrhage, and it is not uncomfortable as the patient is under cocaine anesthesia. It should be dropped on the wound carefully and slowly so that it will not run down into the pharynx and make the patient cough. One might use a fine Eustachian catheter, on the wider end of which a small rubber bulb (a dropper) is mounted and fastened air-tight with a rubber band. One filling of the bulb with collodium is usually enough to cover the whole wound.

89. **Trichloracetic Acid.**—Schwabe has investigated the action of trichloracetic acid on the mucous membrane. He finds that it acts only superficially, but destroys the epithelium, and is an excellent means for producing this effect. Galvanocaustic scabs are favorably influenced by the application of this acid. It seems also to be useful by forming a superficial protective layer that prevents the settling and developing of those

bacteria which have entered the nose within the region deprived of its physiologic protection. Its property of closing up all the channels discharging from the surface of the turbinals renders it applicable in the treatment of hay fever. He has employed it in numerous cases of nasal hydroporrhea with excellent results. The acid apparently enters into combination with the albumin of the glandular duct secretion, and thus prevents the fluid from being discharged for several days.

94.—See abstract in *THE JOURNAL* of November 8, p. 1205.

95.—See abstract in *THE JOURNAL* of November 8, p. 1204.

97. **Pseudo-Rheumatism.**—A number of conditions resembling rheumatism are reviewed by Walsh, who concludes that acute articular rheumatism would seem to be an acute infectious disease and with no more necessary relation to such pathologic changes in joints, as are exhibited in milder or severer forms of arthritis deformans, than certain other infectious diseases. The so-called chronic rheumatism, with degenerative changes in joints, partakes rather of the nature of arthritis deformans than of a true rheumatic process, and should be treated accordingly. Muscular rheumatism, so-called, is usually not an acute infection in any way similar to acute articular rheumatism, but the painful conditions in muscles spoken of as rheumatism are really due to blood dyscrasia and certain toxemias, or to functional arthritic nervous conditions, causing reflex pain in muscles around joints, or to certain occupations in which muscles are overused or improperly employed, and finally to such joint relaxations as occur from flat-foot or dislocation or frequently repeated or severe sprains.

98.—See No. 72 above.

103. **The Heart in Pneumonia.**—The importance of an examination of the condition of the heart in pneumonia is insisted on by Wainwright, who describes the mechanism of dilatation and failure of the right heart in this disease. Its hypertrophy may be an important factor in producing pneumonia and other pulmonary diseases. He calls attention to one especially valuable physical sign, the pulmonic element of the second sound of the heart, which is underestimated by the profession. In young children this element is accentuated, and at the middle period of life the pulmonic and aortic are about equal in intensity, while in old age the aortic element becomes accentuated under normal conditions. In pneumonia, this well-pronounced accentuated second pulmonic sound becomes a safe guide for the administration of cardiac stimulants and aids in making an intelligent prognosis. A diminution of intensity of this sound is a confession of failure of the right heart, and should be a signal for the use of digitalis, alcohol and other cardiac stimulants. The rapid and weak pulse is not so reliable. He speaks in regard to the use of digitalis, that when not indicated it is a pernicious drug, but when it is really indicated nothing is better. In the discussion following Prof. Andrew H. Smith takes a somewhat different view as regards the use of digitalis, holding that it has often done more harm than good. Its use is pernicious except when there is arrhythmia, indicating heart failure, then it may be of use to steady it.

108.—See No. 72, above.

109.—*Ibid.*, November 15, title 26, p. 1278.

115. **Diagnosis of Tuberculosis.**—The points specially called attention to by Milroy are the need of care as to the clinical history, symptoms of failing strength without assignable cause, indigestion, increased heart action, cough with or without expectoration, hemorrhage and a careful study of the temperature. He agrees with Hobbs that all cases with a mean temperature of 99.5, which is not much above the normal range, are predisposed to tuberculosis. The two diseased conditions with which incipient phthisis are most frequently confused are probably malarial fever and dyspepsia. He notices particularly the need of attention to the quality rather than the quantity of sound in percussion and the securing of proper breathing on auscultation. The disease is especially liable to manifest itself about two inches below the middle of the sternum in front, or in the suprascapular region behind or in the apex of the lower lobe behind or the apex of the right

middle lobe, which is found in the midaxillary line at the fourth interspace.

117. Tuberculosis.—Johnson recapitulates the argument that the preponderance of evidence indicates that the germs rarely if ever reach those portions of the lungs, which are most frequently the seat of primary tubercular foci, through the air current, but usually through the circulatory system. It does not necessarily follow that they are absorbed from the walls of the air passages, but that they might have been absorbed at other points, as the alimentary tract. The primary foci of pulmonary tuberculosis in man are most frequently in the smaller lobes of the lungs, which are frequently in a collapsed condition and where germs would be less likely to enter through the air channel. Their seat indicates an abnormal condition of the parts at the time of attack rather than the source through which they entered the system. Koch's statement that inhalation is the chief cause is, therefore, erroneous.

120. Technic of Prostatectomy.—The method described by Bryson is the perineal one, in which, after the introduction of the staff, he makes a free median incision in such a way as to open the urethra just in front of the apex of the prostate. The forefinger is introduced and the staff withdrawn. Guided by the finger a blunt instrument is passed into the urethra and made to puncture, from the urethral side, the lowermost part of the mass. The puncture is always made in the lower posterior quadrant, and the instrument pushed well into the swelling. The finger follows, tearing its way in the opening through the capsule and loosening the lobe as far as its attachment to the urethra from which it is detached, care being taken not to take away too much of the sides nor any of the roof of the urethra. The hypertrophied lateral lobe is then removed. The process is repeated on the opposite side, after which a median posterior segment sometimes remains to be dealt with, which can easily be excised. Usually the finger can be then passed into the bladder, which is explored. The cavity is irrigated with a hot salt solution and a loose flap of mucous membrane found that can be made to occlude the vesical vault. Care should be taken not to push this back into the bladder when a large drainage tube is introduced and the cavity packed with gauze. This technic is modified to some extent according to the size of the prostate, as the incision must be made to correspond. In some later cases he has done a preliminary epicystotomy for drainage and for the treatment of the bladder and kidneys, and he thinks it is best, when this is to be done, to make it a preliminary operation.

121.—See abstract in *THE JOURNAL* of July 5, p. 40.

122. Middle Cranial Fossa.—Bartlett describes the anatomical conditions in the middle cranial fossa with special reference to the occurrence of the middle meningeal artery. He finds it impossible to formulate any rule for avoiding this in making a bone opening for removal of the Gasserian ganglion. It can hardly be said to follow the same route in any two cases. We should realize the possibility of meeting the artery at almost any point in the temporal fossa or even outside the protecting wall. He also calls attention to the faulty description of the field of operation. He describes certain anomalies of the meningeal artery and says that this vessel is most easily avoided at the point where it enters the cranial cavity. He also notices those cases which have the second and third branches of the trifacial closest together.

123. Gastroenterostomy.—Fowler has devised a method of gastroenterostomy, which consists of first securing a communication between a loop of the jejunum and the stomach, then an entero-enterostomy between the afferent and efferent portions of this loop, and finally, obliteration of the lumen of the afferent loop between the two points of the anastomosis, by passing a No. 20 silver wire two or three times around the afferent loop at the point selected, and drawing on the turns sufficiently to occlude the lumen without strangulating the wall. The ends are twisted together, cut short and rolled into a flat coil in such a way as to bring the cut ends in the coil, thus guarding against subsequent injury to the surrounding structures. He reports cases.

124. Hypertrophic Tuberculosis of the Intestine.—After a detailed description of the conditions in a case, Harris discusses the etiology, morbid anatomy, symptomatology, diagnosis, prognosis and treatment. Of course, it is only capable of operative relief. The statistics as regards operation are on the whole encouraging. There were 60 cures and 4 cases improved out of a total of 88 operated on.

125.—See abstract in *THE JOURNAL*, xxxviii, p. 1467.

126. Fracture of the Neck of the Femur.—Whitman criticises the familiar methods of treatment of this injury, which he says is misrepresented in text-books as being uncommon, excepting in old age. The methods, he thinks, are faulty both in conception and practice, if intending reposition and retention of the parts in the normal position. Abduction of the thigh would be much more likely to bring the parts into position than when the limb is held on a line with the body. If reposition were attained it could be kept secure with the long spica bandage with fixation in abduction. He has also modified the after-treatment of some of these cases, using the ordinary hip splint as a traction appliance, or as a simple perineal crutch in after ambulation. When replacement is impracticable as in the ordinary type of coxa vara, he would remove a wedge of bone from the base of the trochanter, preserving a portion of the cortex at the apex of the wedge on the inner side of the femur, opposite the trochanter minor, and then retain the limb in the position of complete abduction until union is complete.

130.—*Ibid.*, September 27, p. 790.

131.—*Ibid.*

132. Pelvic Suppuration.—Williams pleads in this article for the abdominal over the vaginal operation. He says that, with all that is said about the simplicity of puncture method and drainage by the vaginal route, with speedy relief and recovery, he wishes to say that aside from the mortality, which is not small, the number of invalids leaving the hospital is very large, and the number that return for subsequent operation is also great. The mortality is smaller and recovery more satisfactory by abdominal section.

153. Affections of the Nails.—After first noticing the rarity of typical onychomycosis trichophytina, the difficulties of its diagnosis and the unsatisfactoriness of treatment, Levisaur mentions a special form of nail disease and the probability of its parasitic origin, though he has not been able to isolate any vegetable parasite. The individual lesions are minute, round, shallow holes of the size of a very small pinhead, arranged sometimes in regular concentric lines, covering sometimes the whole surface of the nail-plate. When recovery occurs it starts from the proximal end and they slowly disappear. The nail is not shed. The cases in which he has observed it are all adults; five of the nine cases had seborrheic eczema of the scalp or elsewhere. Pruritus, especially of the anus, seemed to be a common accompaniment. Salves seemed to have little effect, and frequent manicuring aggravated the disease. In four cases cure was produced by the use of a 1 per cent. solution of permanganate of potash; bathing with this for about ten minutes twice a day, followed with an oxalic acid solution (2 per cent.). He is inclined to think that the disorder has some connection with Unna's seborrheic eczema, but no relation with ringworm or psoriasis. The occasional combination of the pathologic

changes of the nails and pompholyx seemed to have escaped the attention of others, but he has observed a number of cases where the matrix of the nails was affected. Ordinary eczema localized on and around the nails is usually readily recognized. He also notes occupation diseases of the nails. Favus of the nails is not nearly so rare as ringworm and is more easy to diagnose. He thinks avulsion of the nails is indicated where the disease has made much inroad. For the milder cases a saturated solution of potassium iodid and metallic iodine may effect a cure. Caustics should be avoided. Koilonychia is, he thinks, due to pathologic changes of the nail bed. As to onychorrhexis it is uncertain whether it is to be called a disease of the nails or only a nervous trophic symptom.

154. Nevo-Carcinoma.—Ravogli reports two more cases of nevo-carcinoma and discusses the condition. He concludes that the nevi frequently cause the carcinoma, not by any included embryonic cells, but because of the frequent bruises and irritations to which they are exposed.

158.—See No. 72 above.

160. Personal Injuries.—Both sides of the personal injury question are shown up by Lodge. He gives instances of the mania for litigation and the methods of many of the plaintiffs and also of the questionable methods adopted by the companies in meeting these attacks. He sees no remedy but one, that is, absolute honesty on the part of all parties, jurors, plaintiff, defendant, judges and expert witnesses.

161. Postmortem from the Medicolegal Standpoint.—The necessity of a thorough postmortem as a furtherance to justice, etc., is insisted on by Lane, who severely criticises some cases that have occurred, including the Luetgert case in Chicago, for instance, with its wild and extraordinary claims on the part of so-called experts.

163.—See above title 139.

167. X-Rays.—Brokaw's article is fully illustrated with pictures of the results of the x-ray treatment. He offers the following points from his six years' experience: Much study is required; the method can not be learned quickly. The most efficient apparatus should be used. When great penetration is necessary high tubes should be employed, and the most powerful coils, capable of generating sparks at eighteen or twenty inches. He holds it will soon be recognized as a proper procedure to subject all inoperable cases to the rays, not in a haphazard manner, but with the tube carefully adapted to each particular case. It is also good practice to subject all patients to the x-rays after operation as a prophylactic measure, and he especially advocates this in case of mammary cancer. He does not object to setting up a dermatitis, but brings this about as soon as possible. He always tans the parts, however, before he actually attacks the growths with a hard tube, if the use of such is indicated. To avoid unfortunate results, white gangrene, etc., one must proceed with caution. Idiosyncrasies are not to be forgotten. He has noticed a susceptibility to the rays in cases of chronic rheumatism, in elderly subjects with faulty vascular conditions, such as senile changes, and in certain alcoholics. The practice of using a high tube from time to time often hastens and brings about curative effects in a most rapid and satisfactory manner. In growths of a considerable area it is well to direct the rays to the periphery as that is where the healing commences most actively.

168. Gynecologic Diseases Without Local Symptoms.—From a review of the literature and a study of the reported cases, Gellhorn offers the following conclusions:

1. Diseases of the female sexual organs occur sometimes without local symptoms, but at the same time may produce disturbances in remote organs.
2. If these disturbances are transmitted by way of the nerve tracts they must be considered to be genuine genital reflex neuroses and can be differentiated from hysterical manifestations.
3. Not every ailing woman should be subjected to a gynecologic examination at once. But in the absence of sufficient cause elsewhere, or when a rational treatment has proved ineffective, the possibility of pelvic disease should be borne in mind.
4. In the climacteric woman a gynecologic examination should be early made in every somewhat suspicious case to facilitate the discovery of the possible existence of a malignant growth and to ameliorate the otherwise grave prognosis by the introduction of an adequate treatment.

182.—See title 72 above.

188. Endocarditis.—The conditions in which endocarditis occurs, its cause, and consequences are discussed by Chapman, who reports cases showing its effects. He insists on the importance of heart complications in disease, both as regards the immediate and ultimate outcome. The teaching that endocardial changes are of but slight consequence, and that little can be done in treating heart cases, and that digitalis is the beginning and the end of cardiac therapeutics, are mischievous, as they set at naught the results of many observers and investigators, and lack the optimism which should characterize all research. Minuteness of observation, discrimination in therapeutics and careful attention to the details of treatment only can bring clinical results.

189. Anesthetics.—The fatal cases of anesthesia are classified by Miller under the following heads: 1. Those where the anesthesia was blamed because no other cause of death was recognized. These are only of interest because of their frequency. 2. Cases in which the effect of the anesthetic on organs already diseased hastened the inevitable fatal termination. This mortality can be diminished by careful preliminary examination and preparation of the patients and by attention to the selection of the particular anesthetic to be employed. Instead of sticking to ether in every case, we have at our disposal cocaine, which has an indefinitely wide field of usefulness, nitrous oxid with practically no mortality for brief operations and sometimes longer ones, and chloroform, which may be safer in certain conditions as in the young and very old, kidney and lung disease, diabetes, in the obese, in dyspnea from any cause, narrowing of the larynx, and in operations about the brain and mouth. The combination of oxygen with ether or chloroform may save patients who can not otherwise undergo the anesthetic. In the third class where deaths are due to improper administration or overdose of anesthetics the difficulty is twofold, and consists of inappreciation of the potency of the agents employed and in a lack of understanding between surgeon and anesthetist. Medical schools slight the subject, hospitals pay little attention to it, in private practice anesthetics are daily administered by those who have no experience and have not studied or interested themselves in the subject. Bungling administration, overloading the lungs with the anesthetic at any one time are responsible for some of these cases. The anesthetist should have a thorough knowledge of the physiologic action of drugs, and there should be no misunderstanding as to the immediate responsibility. He is in a better position to observe the general condition of the patient than the operator, and should have chief consideration in this respect.

1. **Intraperitoneal Hemorrhage.**—Cullingworth's article reviews the whole subject of intraperitoneal hemorrhage from ectopic gestation, which is its usual cause. He notices the symptoms and discusses separately peritoneal hematocoele, which he credits as usually the result of bleeding from an ectopic pregnancy in the fimbrial end of the tube before it is thoroughly closed up. He points out the dangers of the neglected ovum and insists on the importance of the diagnosis of these conditions.

2. **Gallstones.**—The operation for gallstone here given by Morison is making a skin incision one inch below the tip of the twelfth rib, ending in front of the middle line, at the upper part of the middle one-third of a line drawn from the ensiform cartilage to the umbilicus. All the layers of the abdominal wall, including the rectus muscle, are divided, and the cut edges of the peritoneum caught in clip forceps. A thick gauze pad or sponge is then packed into the abdomen under the lower flap of the wound over the colon and omentum, shutting off access to the general peritoneal cavity in this direction, and on the inner side and in front the stomach is covered and protected by a gauze pad. The wound may be more thoroughly opened out by making the ileocostal space convex to the right and pushing the hips and shoulders to the left. Drainage is secured by a rubber tube, which in case of the gall bladder is fixed to it by catgut sutures and a thick broad strand of gauze through the wound posteriorly to insure its patency. Drainage of the common duct is effected by leaving an opening in the duct unsutured with a large tube apposed to it. He does not favor drainage of the hepatic and common ducts by tube in the lumen. The wound is closed with four tiers of catgut or with two of catgut and two of silkworm gut, the first bringing together at the sides the peritoneum, fascia, transversalis and

internal oblique muscle; the second the external oblique, the third secures the fat and skin subcutaneously to the external oblique, while the fourth is a subcuticular for the skin edges. When a silk-worm gut is used, the first layer of deep, far-distanced, interrupted sutures attach the skin to the external oblique muscle and bring the skin edges together roughly. The second intermediate interrupted suture through the skin edges completes the apposition, and in front the rectus and aponeurosis receive the same care. He tabulates and discusses his cases. They confirm the surgical belief that in most cases operation affords permanent relief and great improvement in the general health. Recurrence of symptoms means gall-stone trouble again.

3. Enlargement of the Prostate.—Freyer reports 6 cases of suprapubic operation for prostatic hypertrophy. He has performed the operation on 21 patients, varying in age from 58 to 79 years; the parts removed weighing from 1½ to 10½ ounces. All of them were advanced cases in catheter life, and in 19 of the cases an absolute and complete cure was obtained. One patient died in acute mania the twenty-fourth day after the operation, and the remaining case succumbed to heat stroke.

4. Perineal Prostatectomy.—Syms describes his method with his rubber retractor, the various advantages of which he points out. Its bulb acts as a hemostatic as well as holding the instrument in place. He objects generally to the suprapubic method, as he considers the perineal one safest and best. He has operated on 21 patients and has had no deaths. All had cystitis except one. A practical cure has resulted in every case except one, where the operation was incomplete.

5.—This article appeared in *THE JOURNAL* of November 8, p. 1182.

6. Urethral Diseases.—The details of the diagnosis of urethral diseases, including personal history, examination of patient generally, the urethral discharge, preparation of specimens, discharge of urine and its examination, urethral exploration and also examination of seminal vesicles and prostate are all included. The details are too numerous to be included here.

8. Renal Decapsulation.—Edebohl describes his well known method and reports cases operated on for other reasons than to cure chronic Bright's disease. He has yet to see the first (vital) effect attributable to decapsulation as such. The final results of some cases have been reported and others will be, later.

9. Blood Count in Abdominal Disease.—Longridge can not regard leucocytosis as an infallible indication of the presence of pus, but as an indication of toxemia its value appears to be very great. An increasing leucocytosis is, other things being equal, the most scientific means at our disposal for gauging the increasing virulence of an appendicular affection and a decreasing leucocytosis is evidence of decreasing virulence or walling off of the toxic products.

10. Intestinal Anastomosis.—Bishop describes a new bone bobbin, which he thinks has the advantages of the Jessett and Allingham bobbins, which, together, meet most of the indications required, simplicity, durability and absorbability, properly uniting the gut, facilitating and protecting suture, etc. He gives figures of the forms for end to end, side anastomosis and pylorotomy, and reports cases of its use.

12. Paraffin Prothesis.—A number of cases are reported by Downie, who finds it valuable and promising in its results. He classifies the failures in this operation to be due as follows:

1. To insufficient antiseptic precautions. 2. To the want of suitable apparatus. 3. To the injection of an excessive quantity of paraffin. 4. To insufficient digital pressure around the nose while the paraffin is being injected. The first two causes are apt to result in local inflammatory mischief, while the two latter favor the escape of the paraffin into the loose cellular tissue in the near neighborhood of the nose.

13. Femoral Hernia.—The operation recommended by Nicoll consists of two parts; 1. Obliteration of the sac, the steps of which are: 1. Exposure of the sac; 2, opening it longitudinally in its middle line and clearing it of contents; 3, separating it from the parts surrounding its neck, including the transversalis and iliac fascia for one inch round the abdominal aspect of the ring; 4, bisecting the sac longitudinally from the fundus

to the neck; 5, making an aperture in one-half near the neck; 6, interlocking the halves by putting the other through the aperture. In some cases it lies better if previously twisted one-half turn on its longitudinal axis; 7, reducing the whole sac through the femoral ring into the extraperitoneal space previously cleared for it by detaching its neck from the abdominal aspect of the ring. The sac thus lies bunched up within the abdomen, between the peritoneum and the transversalis and iliac fasciæ over the internal aperture of the femoral canal. II. Closure of the femoral ring consists in: 1. Carrying an incision (bone deep) from the femoral vein along the pubic ramus to the region of the pubic spine, dividing the pubic portion of the fascia lata and the origin of the pectineus, and the periosteum. Its length will depend on the extent to which the femoral vein has been displaced outward by the presence of the hernia, and will vary from 1 to 1½ inches. 2. Detach the periosteum to a limited extent and retract it. 3. Drill the bone in its upper edge in two places, one half to one inch apart. 4. Pass through one of the apertures a loop of stout catgut or other absorbable ligature. 5. Divide the loop of ligature. Thread one end in a large curved surgical needle and pass it as a mattress suture through Poupart's ligament. Unthread it from the needle. Repeat this with the second end, carrying it through Poupart's ligament at a higher level, avoiding the deep epigastric artery to the outer side, and, in the male patients, the spermatic cord above. In very large hernias the loops may be made to diverge in the ligatures so as to gather in the margin of the aperture. 6. By a probe, into the eye of which the ends are threaded, withdraw both through the second drill-hole of the bone. 7. Tie the ends of each loop separately over the front of the bone, thus bringing Poupart's ligament down to the posterior surface of the bone, and then fixing it firmly in contact with that surface, thus making an extension practically of Gimbernat's ligament. 8. To more fully secure a closure, unite, by interrupted catgut sutures, the detached margin of the pectineal origin and the pubic portion of the fascia lata to the anchored Poupart's ligament. He asserts that this method has advantages over the Roux method in that it avoids the introduction of any metal body, and in other respects.

14. Rodent Ulcer.—McFeely treats rodent ulcer with formalin under local or general anesthesia, if it is not very large or easily accessible. Two or three applications seem necessary. Later he uses formalin glycerin 30 to 50 per cent., with or without tannin. In long standing cases liable to involve bone or extensively destroy tissue he prefers to first curette away the diseased tissue, apply hemostatic and then apply the formalin, all under anesthesia. The formalin should not be allowed to evaporate. The blackish slough should be allowed to separate spontaneously or may be assisted by some unirritating ointment. He speaks highly of the results of this treatment.
